Ying Xie<sup>§</sup>

## Abstract

We investigate the relationship between viewing modus (low and high intensity viewing) and consumers' engagement with media franchises in two areas: personal and interactive engagement. The former involves consumers' adoption and consumption of franchise extensions and the latter concerns consumers' content generation related to a focal media product they watched. Our novel data come from an online anime (Japanese cartoons) platform containing individual-level information on consumers' anime watching behavior and their user-generated content. We find that the effects of high intensity viewing on personal engagement critically depend on the availability of a franchise extension at the time of watching the focal media product and the type of franchise extension (sequels versus other types of extensions). For interactive engagement, our results show that high intensity viewing is associated with lower submission rates but higher valence of anime ratings, the most prevalent form of UGC on the platform. Furthermore, we explore five common sources of heterogeneity: age, gender, geography, usage, and experience. We discuss managerial implications for TV networks and online streaming services regarding the timing of content release.

**Keywords:** Viewing Modus, Media Consumption, Binge-Watching, Media Franchise, Consumer Engagement, Online Movie Streaming

# 1 Introduction

The global at-home media entertainment industry has fundamentally changed during the last 15 years due to online streaming, a new technology brought about by high-speed Internet. Prior to online streaming, at-home media consumption was mostly characterized by “appointment watching” or “linear watching” of TV programs, i.e., consumers turning to a specific TV channel to watch a show on a day and at a time determined by the TV network. While appointment watching still exists, its importance has declined. At-home media consumption through TV channels and satellite TV has been – to a large extent – replaced by over-the-top (OTT) media consumption.<sup>1</sup> OTT media services allow consumers to freely choose when and how much of a movie or TV series to watch. Consumers have overwhelmingly embraced this new technology giving rise to new media consumption behaviors such as “binge-watching,” which is characterized by rapid consumption of media content in a short period of time. This new technology has also changed the structure of the at-home media entertainment industry: streaming services such as Netflix and Hulu have emerged as major players in distributing and creating media content, traditional TV networks have launched their own streaming platforms, and new contenders such as Apple and Disney have just launched their OTT services.<sup>2</sup>

Another notable trend in the entertainment and media industry is the rising success of media franchises on both big and small screens.<sup>3</sup> We define “media franchise” as a collection of media products in which several derivative works have been developed in response to the popularization of an original creative work and the commercial exploitation of such through

---

<sup>1</sup>An OTT media service is a streaming service that delivers film, TV and video content directly to viewers over the internet without requiring users to subscribe to traditional cable or satellite pay TV. In 2015, over 40% of U.S. households subscribed to at least one video streaming service (<http://www.nielsen.com/us/en/insights/reports/2015/the-total-audience-report-q4-2014.html>). 70% of North American internet traffic in 2015 consisted of streaming video and audio content and Netflix alone accounted for 37% of all internet traffic in North America (<https://www.sandvine.com/pr/2015/12/7/sandvine-over-70-of-north-american-traffic-is-now-streaming-video-and-audio.html>).

<sup>2</sup>In a recent article from November 9-10, 2019 titled “There will be blood,” the Wall Street Journal quotes two industry experts as saying “The next 18 months is going to be the most interesting in the history of the entertainment business – the grounds are shifting” and “This market is going to have to shake out – it doesn’t feel like all these players can continue to play this game forever”.

<sup>3</sup>In 1994, 1 out of the 10 top grossing movies was a franchise. In 2014, 7 out of the 10 top grossing movies were franchises (<https://www.ft.com/content/192f583e-7fa7-11e4-adff-00144feabdc0?mhq5j=e5>).

licensing agreements (Aarseth 2006). For example, the three top-grossing movies of 2015 all belonged to franchises such as “Star Wars,” “Jurassic World,” and “Avengers.”<sup>4</sup> Franchise series also ruled the small screen as witnessed by the exploding traffic on Netflix drawn to “Breaking Bad” and “House of Cards,” original series created by the streaming service.

Anecdotal evidence and common industry practices suggest that consuming media content at a high intensity might increase viewer engagement with media franchise series. For example, “Breaking Bad” creator Vince Gilligan previously told Mashable that the show “may have met its demise after season two, had it not been for streaming video on demand. It ushered in new viewers and encouraged time-starved individuals to keep watching at their own pace resulting in enormous growth from season to season” that reached its climactic end in September 2013 with 10.3 million viewers (the show’s highest viewership ever) (Hernandez 2014). Similarly, for popular series such as “Supernatural,” Netflix starts streaming previous season(s) shortly before the release of a new season (on traditional TV).<sup>5</sup>

However, there is little systematic examination into the relationship between a consumer’s media consumption intensity and her engagement with a media franchise. In this paper, we aim to fill this gap. To do so, we differentiate between two media consumption modi: low-intensity viewing (LoVi) and high-intensity viewing (HiVi). We define LoVi as “slow” or gradual watching (of a series) over a longer time period. This definition encompasses both appointment watching (on TV) and consumer-driven slow viewing of a series (through an OTT service). In contrast, we define HiVi as “fast” or “intensive” watching of a series over a short time period. This definition applies to both marathon releases (on TV) and consumer-driven intensive viewing of a series (through an OTT service). HiVi includes, but is not restricted to binge-watching.<sup>6</sup>

---

<sup>4</sup>The total historic revenue from the “Star Wars” franchise was \$42 billion (by 2015), \$25 billion (by 2016) for the “Harry Potter” franchise, and \$6 billion (by 2016) for the “Ice Age” franchise.

<sup>5</sup>The empirical context of this paper are anime (Japanese cartoon) series. Thus we use the terms “next season” and “sequel” interchangeably.

<sup>6</sup>Recently, a process-based definition of binge-watching has been suggested (see, e.g., Schweidel and Moe 2016, Lu et al. 2017). It poses that streaming data are necessary to classify viewing behavior as binge-watching, i.e., the researcher has to observe that a consumer watched at least two episodes of a series directly in a row. Our data contain information on how many minutes of a series a consumer watched on average per day, but we do not observe whether this watching happened in one sitting. For more details, please see Sections 2.2 and 3.1.

To measure consumer engagement with media products, we adopt the categorization developed by Calder et al. (2009). They identify two types of consumer engagement: “personal engagement” such as enjoyment and relaxation directly derived from consuming the product and “interactive engagement” such as socialization and participation in a community facilitated by consuming the product. Calder et al. (2009) associate the former with an individual’s internal state of getting caught up in the flow of an activity and being absorbed by it (Csikszentmihalyi 1997) and the latter with an individual’s voluntary content generation and promotion of a focal media product. Therefore, increased engagement with a TV series might result in the viewer watching subsequent seasons or other types of franchise extensions<sup>7</sup> of the same series (i.e., personal engagement) and/or in the viewer promoting the TV series and producing user-generated content (UGC) about it (i.e., interactive engagement).

In this paper, we empirically examine whether intensively watching a focal media product indeed increases personal engagement by enhancing a consumer’s adoption and consumption of other media products belonging to the same franchise. At the same time, we also investigate whether watching intensively affects consumers’ interactive engagement by altering their content generation behaviors related to the focal media product. If HiVi increases consumers’ engagement with a media franchise, this finding would have important implications for both online streaming services and traditional TV networks. For online streaming services, it would validate their practice of releasing a whole season of a series at once and thereby making it bingeable. For TV networks, it would provide support for their new strategy of promoting a new season shown on traditional TV by making older seasons available through online streaming

---

<sup>7</sup>We study five types of franchise extensions in this paper: sequels, side stories, spin-offs, summaries, and remakes. Frequently, we divide franchise extensions into two groups: sequels and “other types of franchise extensions” (i.e., side stories, spin-offs, summaries, and remakes). A “sequel” is a story that is a direct continuation of the focal series and usually carries on elements of the original story, often with the same characters and settings. For example, season 8 of “Game of Thrones” is a sequel to season 7 of “Game of Thrones.” A “side story” is a short story related to the main characters in the context of the focal series. For example, the movie “Sherlock: The Abominable Bride” is a side story for the “Sherlock” series. A “spin-off” is a story taken from the focal series, however, unrelated to the main story. It usually tells the story of a secondary character following a different storyline, almost like a new series. For example, the “Joey” series is a spin-off from the popular sitcom series “Friends.” A “summary” is a short series or a movie summarizing the events of the focal series. For example, the “Pink Panther” movie is a summary of the events in the identically titled TV series. A “remake” is a remake of the series, usually with small differences in the plot or a different ending. For example, there are several “Batman” series that are remakes of the same story.

services. This strategic tool could represent an especially important benefit for TV networks since it would not only increase immediate profits through higher advertising revenues (for the new season on traditional TV), but also extend the “life” of a series, making it more likely to reach five seasons at which point the series is a candidate for syndication, a very profitable path for networks.

If HiVi does not increase media franchise engagement or if it does not do so for all shows or all consumers, it is important to understand when and why this is the case. Does the timing of the release through online streaming services matter? Or does the type of franchise extension matter? Furthermore, given the varying popularity of online streaming and HiVi across different countries and consumer segments, are consumers with certain characteristics more susceptible to the effect of HiVi than other consumers? In this paper, through a systematic empirical investigation, we provide a description of this new viewing modus and its relation to consumer media franchise engagement.

Our data come from MyAnimeList.net, an online forum that attracts anime (Japanese cartoons) fans from all over the world. We observe an individual’s adoption timing of anime series including the number of days it took a consumer to watch the whole season of an anime. This information allows us to classify consumer-anime combinations into “HiVi” and “LoVi” cases. Further, we observe an individual’s self-generated content about an anime in the form of published posts on the discussion forum as well as submitted ratings and recommendations. Our data also contain information on a consumer’s decision to watch the next season (sequel) of an adopted anime and/or to watch other types of franchise extensions. And lastly, we observe a consumer’s demographic and behavioral characteristics, including the individual’s geographic location, age, gender, domain expertise, and recent anime watching activities. These consumer-specific traits allow us to explore whether and how the effects of HiVi vary across different consumer segments.

We mostly use bivariate binary probit models to study the relationship between the viewing modus and a consumer’s actions related to media franchise engagement.<sup>8</sup> The first equation

---

<sup>8</sup>For a few continuous engagement variables, we use a linear regression model together with a binary probit

describes the user’s decision of viewing modus (low vs. high intensity) and the second equation models the relation between high intensity viewing and consumer engagement. Further, we incorporate two exclusion variables that can be interpreted as instruments in the viewing modus equation to account for the potential endogeneity of the decision to watch at high intensity. By simultaneously modeling a consumer’s viewing modus decision and media franchise engagement decision, we also allow correlated unobservables to affect both decisions.

Our results show that the effect of HiVi on an individual’s personal engagement largely depends on both the availability of a franchise extension at the time of watching the focal season and the type of franchise extension. If the franchise extension is available, watching the prior season at high intensity significantly increases a consumer’s probability of watching the subsequent season (sequel), but decreases the probability of adopting another type of franchise extension. If the franchise extension is not available at the time of watching the focal season, HiVi decreases the adoption probability of both sequels and other types of franchise extensions. However, conditional on adopting a franchise extension, we find that HiVi has a significant positive effect on the likelihood of finishing to watch the franchise extension – regardless of the type of franchise extension. In addition, we find that consumers who watch a focal anime at high intensity are more likely to watch a franchise extension immediately next than those who watch at low intensity and that this effect is stronger when the franchise is a sequel (versus another type of franchise extension).

Regarding the relationship between HiVi and interactive engagement, i.e., the production of UGC, we find that the effect of HiVi varies with the type of UGC: it decreases the likelihood of submitting a rating, increases the likelihood of making a recommendation, and does not affect the likelihood of publishing a forum post. Given that ratings are the most prevalent type of UGC and recommendations are very rare on this platform, our results provide partial support for the general avoidance tendency of binge-watchers, proposed and documented in previous literature (e.g., Schweidel and Moe 2016). We also find that consumers who watch at high

---

model allowing for a correlation in the error terms across the two equations, i.e. we use an analogue of the bivariate binary probit model with one of the equations being a linear instead of a probit model.

intensity rate the focal anime higher, suggesting that HiVi positively affects consumers' liking of a media product.

We extend our analysis to explore five common sources of heterogeneity: age, gender, geography, usage, and experience. Geographic heterogeneity is mostly captured by different behaviors of consumers in and outside of North America: consumers in North America are more likely to consume at high intensity, less likely to engage personally, and more likely to engage interactively than consumers outside of North America. We find a limited amount of heterogeneity related to age and gender: older consumers are less likely to watch at high intensity and to produce related UGC than younger consumers. Women are more likely to write forum posts and submit ratings, but these forum posts are shorter and ratings are worse than those written and submitted by men. Our results also indicate that more experienced consumers and consumers with higher recent usage are less likely to consume at high intensity than less experienced consumers and consumers with no recent usage. Lastly, we find that the effects of HiVi on interactive engagement vary with experience and usage: more experienced consumers and consumers with higher recent usage who watch at high intensity tend to generate more forum posts and/or recommendations related to a media franchise than less experienced consumers and consumers with no recent usage who watch at high intensity.

Our paper makes the following two contributions. First, we contribute to the consumer engagement literature by systematically examining the factors that drive consumer engagement in the context of a media franchise. By quantifying the effect of HiVi on consumer engagement with a media franchise in two broad areas – interactive and personal engagement – our paper provides empirical evidence that the modus of consumption, on top of product adoption, influences consumer brand engagement. And second, our paper adds to the small but rapidly growing literature on viewing modus, binge-watching, and online streaming. To the best of our knowledge, we are the first to study the relationship between viewing modus and consumers' subsequent media consumption and word-of-mouth behavior. Our results have important managerial implications for both online streaming services and traditional TV networks regarding content provision and the timing thereof.

The remainder of the paper is organized as follows: In the next section, we present our theoretical framework. In Sections 3 and 4, we describe our data, introduce our model and estimation approach. We present our results in Section 5. In Section 6, we explore five potential sources of heterogeneity and discuss limitations and future research in the following section. Finally, we conclude by summarizing our findings and discussing managerial implications in Section 8.

## 2 Theoretical Background

In this section, we draw from relevant streams of literature on customer engagement with a media franchise, on viewing modus, and on online movie streaming. We then discuss how past research in these three domains informs us about the relationship between the viewing modus and consumer engagement with a media franchise.

### 2.1 Customer Engagement with a Media Franchise

Customer engagement has been extensively studied in the marketing literature (e.g., Bowden 2009; Mollen and Wilson 2010; Van Doorn et al. 2010; Vivek et al. 2012).<sup>9</sup> It differs from similar relational concepts such as participation or involvement in that it highlights customers' interactive and co-creative experiences in networked relationships with multiple stakeholders including service personnel, firms, and/or other customers (Brodie et al. 2011). Table A-1 in Appendix A provides a brief summary of engagement definitions used by previous literature. Empirical studies across various industries have shown that engaged customers play a key role in viral marketing activities by generating referrals and recommendations for products and services, in new product development, and in co-creating experiences and value (e.g., Nambisan and Nambisan 2008; Brakus et al. 2009; Hoyer et al. 2010). However, to the best of our knowledge, no empirical study to date has systematically examined customer engagement in the context of media franchises.

---

<sup>9</sup>We refer readers to Brodie et al. (2011) for an extensive review of the marketing literature on engagement.

To understand what drives customer engagement with media franchises, the first question is how customer engagement with a media product should be measured. In this regard, Calder et al. (2009) define media engagement in terms of the different motivational experiences that consumers have with a media product. Using confirmatory factor analysis, they identify two types of media engagement: personal engagement and interactive engagement. Personal engagement is associated with intrinsic motivation and includes individualistic experiences such as enjoyment and relaxation directly derived from consuming a media product. More specifically, a consumer’s personal engagement with a media product is driven by the “transportation” motive, i.e., by consuming a media product a consumer aims to be transported into a different state (e.g., from bored to happy) or to be transported into taking part in an activity, such as being absorbed into a story and shutting out the real world. Csikszentmihalyi (1997) describes a more general variant of the “transportation” experience as the internal state of an individual getting caught up in the “flow” of an activity and being absorbed by it. Interactive engagement, on the other hand, is associated with extrinsic motivation and includes interactive experiences such as socialization and participation in a community facilitated by the consumption of a media product. For example, after watching a movie, a consumer may have the urge to generate online word-of-mouth related to the movie by submitting a rating, publishing a review, or participating in discussion forums on social media. This online word-of-mouth has been shown to be effective in raising awareness and influencing opinions of other consumers, through which it increases the adoption of the movie (Ameri et al. 2019).

In this study, we follow the categorization by Calder et al. (2009) when examining consumers’ personal and interactive engagement with media franchises. In our empirical context of an online anime platform, we measure a user’s personal engagement with a media franchise by examining her self-enjoyment of the focal media product and the adoption of its franchised extensions including sequels, spin-offs, summaries, side stories, and remakes. We assess her interactive engagement through her content generation and promotion of a focal media product, i.e., her decision to submit recommendations, ratings, and comments in a community discussion forum regarding the focal anime series.

## 2.2 Viewing Modus

We differentiate between two viewing modi: low-intensity viewing (LoVi) and high-intensity viewing (HiVi). We define LoVi as “slow” or gradual watching (of a series) over a longer time period. This definition encompasses both appointment watching (on TV) and consumer-driven slow viewing of a series (through an OTT service). In contrast, we define HiVi as “fast” or “intensive” watching of a series over a short time period. This definition applies to both marathon releases (on TV) and consumer-driven intensive viewing of a series (through an OTT service).

HiVi includes, but is not restricted to binge-watching, i.e., the practice of watching multiple episodes (of a series) in one sitting.<sup>10</sup> Table A-2 in Appendix A provides a summary of binge-watching definitions used by previous literature. We note from Table A-2 that there is disagreement on how much watching is considered binge-watching. Based on a survey of their users, Netflix defines binge-watching as watching at least two episodes in one sitting (Netflix 2013). The number of two episodes is not agreed upon by everyone though. For example, Amazon made the first 3 episodes of its series “Alpha House” available to its viewers at once, implying that it considers 3 episodes as a bingeable amount. Schweidel and Moe (2016) and Lu et al. (2017) use process-level streaming data to define binge-watching. For example, Schweidel and Moe (2016) consider “the consumption of multiple episodes of a television series in a short period of time” as binge-watching. Other studies rely on respondents’ perception of what is considered binge-watching without defining a specific amount (e.g., Devasagayam 2014; Pena 2015).

These definitions rely on the number of episodes without differentiating between one-hour dramas (about 40 minutes without commercials) and 30-minute sitcoms (about 20 minutes without commercials). It is debatable whether watching 8 episodes of a sitcom corresponding to about 2.5 hours should be considered as binge-watching. To circumvent these obstacles, in

---

<sup>10</sup>Many regard the element of control, i.e., the consumer’s control over whether to watch more episodes, as an essential part of binge-watching. In other words, binge-watching is not only about watching multiple episodes in one sitting, but also about a consumer’s control and decision of when and what to watch. Thus a consumer watching a marathon release on TV would *not* count as binge-watching.

this study, we suggest a clear definition of HiVi which is based on the time spent watching a whole season and also test its robustness (see Web Appendix B). This definition is in line with the idea that HiVi is a violation of what is considered the norm, regular TV watching such as "appointment watching" or "linear watching," which we classify as LoVi.

The underlying mechanism that drives HiVi is related to the concept of flow (e.g., Hoffman and Novak 1996), which describes a state of focused concentration, intrinsic enjoyment, and time distortion. Previous research has found that users who experience the flow are more likely to repeat their behaviors or even become addicted (e.g., Kubey and Csikszentmihalyi 2002; Chou and Ting 2003). This mechanism also provides a plausible explanation for the interplay between advertisements and binge-watching as documented in Schweidel and Moe (2016): advertisements in a viewing session discourage binge-watching and binge-watchers are less responsive to advertisements compared to non-binge-watchers.

While there has been a considerable amount of research on the reasons for HiVi, few studies have focused on the consequences of HiVi. In the TiVo (2015) study, 52% of respondents indicated that they feel sad when they finish bingeing a series; 31% reported that they have lost sleep due to bingeing. Binge-watching - due to the intensity of the experience and the flow it creates - has been suggested to create loyalty to a series, to lead to fandom, and to help the formation of one-sided, unconscious bonds between viewers and characters or, at the very least, behavior similar to fandom such as purchasing ancillary materials, creating fandom pages or posting or creating content (Devasagayam 2014; Jenner 2015). However, empirical evidence supporting these claims is very limited. To the best of our knowledge, this paper is the first to carry out a systematic empirical examination of the effects of HiVi on consumer engagement with a media franchise.

### **2.3 Online Streaming**

Despite its wide popularity, research on online movie streaming is scarce. Cha and Chan-Olmsted (2012) study the plausible cannibalization effect of online video platforms on tradi-

tional TV. They find that users of online video platforms believe that online video platforms have unique functionality and therefore are not substitutes to traditional TV. However, non-users of online video platforms perceive online video platforms as substitutes for traditional TV because of their perceived similar functionality. Cha (2013) finds that the more consumers perceive online video platforms to differ from traditional TV in satisfying their needs, the more likely they are to use online video platforms.

Studying consumer behavior within online streaming services, Zhang et al. (2013) develop a new class of “clumpiness” measures and, using data from Hulu.com, show that the “clumpiness phenomenon” is widely prevalent in digital content consumption. In a separate study, Zhang et al. (2015) extend the traditional recency/frequency/monetary value (RFM) segmentation framework to include the clumpiness measure (RFMC). In particular, they show that the RFMC framework can help companies with bingeable content (such as online streaming platforms) uncover previously unseen customer segments. Ameri et al. (2019) investigate the drivers of consumers’ anime adoption decisions in the context of online streaming. They find the average anime rating and the popularity rank from the community network, i.e., the platform, to have larger effects on consumers’ adoption decisions than the same two types of information obtained from the personal network, i.e., a consumer’s friends. And lastly and most closely related to this paper, Schweidel and Moe (2016) simultaneously examine the drivers of users’ binge-watching behavior and their responses to advertisements using data from Hulu.com. They find that binge-watchers are less responsive to advertising compared to non-binge-watchers.

## 2.4 Theoretical Synthesis

In this subsection, we provide a theoretical synthesis of prior research based on which we develop a set of predictions for our empirical context. We first discuss the relationship between the viewing modus and personal engagement and conclude this subsection by examining the relationship between the viewing modus and interactive engagement.

HiVi can affect consumers’ personal engagement in two distinct ways. On the one hand,

media consumers who experience the flow created by intensively watching are more likely to repeat their behavior or even become addicted in order to stay in the flow (e.g., Kubey and Csikszentmihalyi 2002; Chou and Ting 2003). One would expect that a natural way for consumers to continue the flow after intensively watching a focal media product is to watch its franchise extensions if they are available (at the time of watching the focal media product). By watching franchise extensions, consumers can remain in the state concentrated around the same characters and their story shown in the focal media product. Therefore, HiVi may elevate consumers' probability of choosing a franchise extension of the focal media product as the *next* media product to watch compared to choosing an unrelated media product next. Similarly, HiVi may also affect the overall likelihood of consumers adopting a franchise extension of the focal media product *at any point in the future*, as a means of continuing the immersive experience and maintaining the one-sided relationship with the characters in the focal media series. And lastly, conditional on starting to watch a franchise extension, HiVi may also increase consumers' probability of finishing to watch the franchise extension so that they can continue staying in the flow.

On the other hand, by watching and finishing a season in a short amount of time, HiVi may also cause "satiation" or boredom with the focal media product. Satiation propels consumers to move away from related media products such as franchise extensions. For example, consumers may seek for variety by watching something unrelated to the focal series *next*, they may completely move away from consuming any franchise extensions of the focal media product *at any point in the future*, and/or they may not finish watching a franchise extension.

These two effects of HiVi on personal engagement work in opposite directions. Therefore the net effect of HiVi depends on how consumers balance the flow created by watching intensively against the satiation that is also brought about by this viewing modus. Whether HiVi enhances or weakens a consumer's personal engagement with media franchises is therefore an empirical question that we set out to answer in this paper.

Among the different kinds of franchise extensions, sequels, i.e. next seasons, are the ones that continue the same story line of and share the same main characters with the prequel or

previous season. Other franchise extensions may have a different story line or may be centered around different characters (e.g., “Better Call Saul” as a spin off of “Breaking Bad” follows the story of a lawyer who was a secondary character in “Breaking Bad”).<sup>11</sup> Therefore, we expect the flow created by intensively watching a media product to be best continued by sequels. In other words, we expect that consumers experience a stronger flow effect when they watch a sequel relative to other types of franchise extensions. However, for exactly the same reason, after intensively watching the focal media product, consumers may also experience stronger satiation when watching a sequel. In the current study, we empirically examine how the net effect of HiVi on personal engagement varies across different types of franchise extensions.

And lastly, we discuss the relationship between viewing modus and interactive engagement. Due to consumers’ inclination to stay in the flow when watching at high intensity, they tend to avoid any activities that distract them from watching the focal media product, including interactive engagement activities such as content creation and promotion of the focal media product. This avoidance tendency is manifested in Schweidel and Moe (2016) where the authors find that binge-watchers are less responsive to advertisements compared to non-binge-watchers. Many industry observers also accredit Netflix’s no disruption design (for example, getting rid of the opening credits at the start of an episode if you are watching more than one episode) as one of the main reasons for the wide spread of binge-watching (Vidar 2015). Thus, we conjecture that consumers who intensively watch a focal media product are less likely to generate related content than consumers who watch the product at a slower pace. However, if these consumer ever generate content about the focal media product, we suspect this content might be more favorable than content generated by consumers who watch at a slower pace. This is because HiVi is suggested to induce loyalty or fandom-like behaviors (Devasagayam 2014; Jenner 2015).

---

<sup>11</sup>Other examples are “Frasier” as a spin-off of “Cheers,” “Joey” as a spin-off of “Friends,” and “The Good Fight” as a spin-off of “The Good Wife.”

### 3 Data

Our data come from MyAnimeList.net. This website is a consumption-related online community where online interactions are based upon shared enthusiasm for a specific consumption activity (Kozinets 1999). It was created to allow anime fans to gather and share their excitement and opinions about animes (Japanese cartoons). This website was established in November 2004, but its main activities did not begin until 2007 when the website moved to a public domain and its user base started to grow rapidly (see Figure 1). At the point in time when we started the data collection in March 2015, there were more than 2.5 million users on the website.

— Insert Figure 1 about here —

On MyAnimeList.net, both animes and users have their own pages. On a user’s page, information about the animes the individual has adopted (including the dates) and her opinion about adopted animes (via numerical ratings, forum posts, and recommendations) is shown in addition to personal information such as the individual’s geographic location, gender, age and the date when she joined the website. Users can create a list of animes that they have watched or plan to watch (we refer to this list as “watch list” throughout this paper).<sup>12,13</sup> Note that users add animes to their watch lists using a search function so that all animes are correctly and uniquely identified. Further, users can also indicate their opinion about the animes on their watch list by rating them on a scale ranging from 1 to 10 (10 being the highest rating). Throughout this paper, we refer to ratings given to animes on watch lists as “ratings.” Lastly, users can indicate the date they started watching an anime series and the date they finished watching an anime series. We use the start and end dates to infer the beginning and end of a user’s watch period for an anime series.

---

<sup>12</sup>We do not account for platform choice in this paper because, in general, users can watch animes either legally or illegally through a number of different channels such as netflix.com, hulu.com, funimation.com, crunchyroll.com, aniplexusa.com and others.

<sup>13</sup>Our adoption data are self-reported. Thus accuracy in the reporting of adoptions is a potential concern. We address this concern when discussing Figure 4. Further note that in contrast to incentivized surveys, there are no incentives for users on MyAnimeList.net to falsely report their true anime watching behavior. Furthermore, in the similar setting of TV shows, Lovett and Staelin (2016) compare survey panelists’ self-reported viewing data and the actual streaming data and find that people tend to correctly report their actual watching behavior. Thus we are confident that the self-reported adoption data are reliable in our context.

### 3.1 Viewing Modus

We define an individual as having intensively watched an anime season if the individual watches the series for over 3 hours a day – a more conservative measure than Netflix’s.<sup>14</sup> To differentiate HiVi from LoVi incidences in our data, we use the average daily time that an individual spent watching a season of an anime series, i.e., we divide the total duration of the anime season (measured in hours) by the number of days that it took the individual to watch all episodes of the anime season. If a user watches more than an average of 3 hours a day (corresponding to about 8 25-minutes long episodes, excluding the few minutes of openings and endings), we mark this incidence as HiVi.<sup>15</sup> In Web Appendix B, we test the robustness of this definition with respect to shorter and longer average daily watch times of 2 and 4 hours, respectively. Our results are qualitatively robust to these alternative operationalizations of HiVi.

### 3.2 Engagement

We investigate three aspects of an individual’s personal engagement with media franchises by examining her consumption decisions related to franchise extensions of a focal anime season. First, intensively watching an anime season might affect a user’s likelihood of watching its franchise extension (at any point in time in the future). Second, conditional on watching a franchise extension, the viewing modus might affect a consumer’s likelihood of finishing to watch the franchise extension. And lastly, if a franchise extension is available at the time of watching the focal anime, watching intensively might also affect the likelihood of watching a franchise extension immediately next versus an unrelated anime. We operationalize these three aspects of personal engagement as binary indicator variables: (i) whether a user watched a franchise extension (at any point in time in the future), (ii) whether a user finished watching the franchise extension (conditional on starting to watch a franchise extension), and (iii) whether a user watched a franchise extension next (conditional on a franchise extension being available).

---

<sup>14</sup>Netflix defines binge-watching as watching at least two episodes in one sitting (Netflix 2013).

<sup>15</sup>Note that a user might have watched more than 3 hours on a Sunday, but it took him Monday to Friday to gradually watch the remaining 3 episodes (about 1 hour) and finish the season. Our data do not allow us to identify the watching behavior on Sunday as HiVi.

We examine an individual’s interactive engagement with media franchises by looking at her decisions to produce UGC related to adopted anime seasons. We investigate three types of UGC: recommendations, ratings, and posts on the discussion forum. Recommendations on this platform exhibit the following pattern: “If you like anime A, you will like anime B because of XYZ.” In that sense, individuals give a recommendation for which two animes are *similar*, but not necessarily a recommendation that an anime is particularly good. Posts on the discussion forum typically discuss topics such as new season release dates, voice cast decisions, story lines, specific characters, awards, or anime adaptations. Ratings are different from the two previously mentioned forms of UGC in that they are numerical and a higher rating clearly indicates a more favorable opinion towards the rated anime season. Furthermore, while ratings are publicly visible to everybody, they are recorded by a user on her watch list and help her remember her preference for or liking of a particular anime.

For each type of UGC, we study whether the viewing modus affects UGC incidence, i.e., whether bingeing affects the likelihood of (a) writing (at least) one recommendation, (b) submitting a numerical rating, or (c) publishing (at least) one post on the discussion forum related to the focal anime season. Conditional on UGC incidence, we further investigate whether the viewing modus also affects UGC valence of (d) ratings or (e) forum posts. In addition, since a user can submit more than one recommendation and more than one forum post about an anime series, we also study whether the viewing modus affects (f) the number of recommendations and (g) the number of forum posts submitted by the individual, conditional on incidence. And lastly, for forum posts only, we also investigate whether HiVi affects (h) the average length of submitted forum posts. Variables (a) - (c) are operationalized as indicator variables and variables (d) - (h) are treated as continuous variables.

### **3.3 Estimation Sample**

We scraped data on 370,000 individuals from the website. Not all users list start dates for (all or any) anime series they have adopted on their watch list. After excluding all user-anime

combinations for which we did not have start dates, we were left with 92,273 individuals.<sup>16</sup> We then dropped (i) animes for which we did not have the release date or information on the number of episodes; (ii) user-anime combinations for which the watch period seemed unreasonably long, i.e. more than 3,000 days; (iii) observations for days on which individuals indicated to have watched animes for more than 24 hours; (iv) observations with start dates before 2008 since, although the website was launched in 2004, its main activities did not start until mid 2007 (see Figure 1); (v) observations with start dates after the end of 2014. Using the remaining 89,422 individuals and 4,896 animes (3,481,664 user-anime combinations), we took the following steps to get to our final data.

First, we dropped anime series for which it would take an individual less than 3 hours to watch the whole season. Table 1 shows the frequency distribution of anime series with respect to their number of episodes and durations of a season in hours. Movies or short anime series generally take less than 3 hours to be watched and thus, according to our operationalization of HiVi, cannot be watch at high intensity. Note that, even if an individual watches 3 movies back to back, if they are not part of a franchise, we do not consider this instance as HiVi. Second, we dropped user-anime combinations in which an individual did not watch the whole season. Even if a user intensively watches the first half of a season (and does not watch the second half of the season), her behavior might be different from someone who intensively watched and finished the whole season. To be able to attribute the difference in user behavior to the viewing modus and not to the completion of the whole season, we only consider cases in which the individual finished watching the whole season.

— Insert Table 1 about here —

Third, we only consider user-anime combinations in which users have the option to intensively watch the anime, but may choose not to do so, i.e., we only consider watching incidences *after* the season finale of an anime has been aired. It is noteworthy that most of our observations are for such cases. In Figure 2, we show the number of days (after the original airing

---

<sup>16</sup>Individuals' behavior on MyAnimeList.net is consistent with the well-known 90-9-1 rule in social media (see, e.g., <https://www.nngroup.com/articles/participation-inequality/>): a large proportion of individuals is inactive.

of the first and last episode in a season, respectively) after which individuals who watched the anime intensively and individuals who watched the anime at a slower pace started to watch it. For example, Figure 2(b) shows that individuals, who slowly watched the anime, did not start watching it immediately after the original airing of the first episode, but instead waited until the season finale aired.<sup>17</sup> Note that access to the anime after its original airing is *not* a reason for the delayed watching: almost all animes are available through online streaming within 3 days of the original episode airing (see also Ameri et al. 2019). And lastly, we dropped individuals for whom we do not have their geographic location. This type of information is needed to control for national holidays and weekends and to explore geographic heterogeneity. After these steps, our final data sample for the empirical analysis of interactive engagement contains 37,694 individuals and 2,562 animes with 693,173 user-anime combinations.<sup>18</sup>

— Insert Figure 2 about here —

For personal engagement, we need to constrain the final data sample further. More specifically, we can only consider anime series that have a franchise extension, i.e., next season (sequel) or another type of franchise extension (i.e. side story, spin-off, summary or remake). After dropping anime series that do not have any franchise extension, the data sample contains 35,447 individuals and 1,250 animes with 490,717 user-anime combinations, i.e. unique user-(focal)-anime combinations. Sometimes, anime series have multiple types of franchise extensions (e.g., a spin-off and a summary). In such cases, we model the adoption of each type of franchise extension as a separate potential adoption. Sometimes, anime series have multiple franchise extensions of the *same* type (e.g., two spin-offs). In such cases, we only model the first potential adoption among franchise extensions of the same type. Because of these two issues, the number of observations in the model estimation is 764,666.

---

<sup>17</sup>A large number of animes have 13 or 26 episodes in a season (see also Table 1). The two spikes around days 91 and 182 after the original airing of the first episode in Figures 2(a) and (b) are consistent with these two frequent season lengths.

<sup>18</sup>Because of missing values in one of our explanatory variables (popularity rank), the number of observations in the model estimation is 663,963.

### 3.4 Data Description

We present summary statistics for the 37,694 individuals in our final sample in Table 2. 20,167 individuals in our final sample report their age. Among these individuals, the average age is 19 years. 42% of users are female and 41% of individuals are male with the remaining 17% of individuals not specifying their gender. 46% of individuals live in Europe, 34% come from North America, 9% from South America, 8% from Asia, and 4% from Oceania. Users, on average, have watched 2 animes during the last 30 days and 57 animes over the course of their membership on the platform. Note that both distributions exhibit positive skewness and long right tails. We use the number of watched animes during the last 30 days to measure consumers' recent product usage and the number of watched animes over the course of the platform membership to measure consumer experience. Further, we find that users, on average, started watching 31% and 3% of the animes on their watch lists on weekends and holidays, respectively. Given that, for example, weekend days represent 28% of days in our data, we observe that users are over-proportionally more likely to start watching animes on weekends (similar results hold for holidays). And lastly, users are significantly more likely to watch intensively on weekends and holidays than to do the same during the workweek or on non-holidays providing support for us modeling the viewing modus decision as a function of the weekend and holiday dummies. For example, on any given day during the workweek and on any given day during the weekend, 13.56% and 16.09% of users, respectively, watch intensively (similar results hold for holidays). To summarize, we find that users are more likely to start watching and more likely to watch intensively on weekends and holidays than during the workweek or on non-holidays.

—— Insert Table 2 about here ——

Figure 3 shows the distribution of watch periods, i.e., the number of days between watching the first and last episode of an anime season, in our estimation sample. In more than 50% of the user-anime combinations, the individual watched a complete anime season within 5 days, with 18.62% of user-anime combinations being watched within a day or two. While Figure 3 does *not* account for the length of a season in terms of the number of episodes, i.e., whether

a season consists of 13 or 26 episodes, or the length of episodes (in minutes), it nevertheless shows the possibility that a significant portion of user-anime combinations might be watched intensively.

— Insert Figure 3 about here —

In Figures 4(a) and 4(b), we display the total number of hours individuals watched animes on a day during which they watched at high and low intensity, respectively (using our 3-hour operationalization of HiVi). Note that the total number of hours in this figure includes *everything* the user watched, i.e. all animes the user watched intensively on that day *and* any other animes the user might have watched on that day. On days during which users watch intensively, the vast majority of users watches between 3 and 6 hours with a second, smaller group of individuals watching between 9 and 11 hours. While the distribution has a long right tail, very few users report watching more than 16 hours a day. This gives us confidence in the accuracy of the self-reported watching behavior (see also Netflix 2013). On days during which users watch at a slower pace, almost all individuals watch less than 3 hours. This is *not* a direct result of our definition of LoVi since Figure 4 shows the total number of hours users spent on watching *any* anime. For example, users who watch 7 20-minutes episodes of one anime series and 7 20-minutes episodes of another anime series would be classified watching at a slower pace on that day, but would have watched more than 3 hours.

— Insert Figure 4 about here —

Figure 5 shows the distribution of the fraction of anime series on a user’s watch list that can be classified as HiVi vs. LoVi using our 3-hour operationalization. About 41.8% of users only engage in LoVi, while for 6.5% of users HiVi is their only viewing modus for all animes. This implies that most of the users choose to intensively watch some anime series while slowly watch others. This empirical observation is consistent with previous findings (e.g., MarketCast 2013; Schweidel and Moe 2016). On average, we classify 20.4% of animes on a user’s watch list as watched intensively with a standard deviation of 28% and a median of 8.3%.

— Insert Figure 5 about here —

Figure 6 displays how the number of HiVi vs. LoVi user-anime combinations has evolved over time. Up until about 2013, both the number of HiVi and the number of LoVi user-anime combinations gradually increased. Starting in 2013, the number of HiVi cases continued to increase, while the number of LoVi cases started to decrease, implying that the proportion of intensively watched animes among all animes a user watches is increasing. This pattern of an increasing proportion of users who watch intensively is consistent with findings reported in several survey studies (e.g., TiVo 2015).

— Insert Figure 6 about here —

Next, we discuss our engagement variables. Table 3 shows statistics for our personal engagement variables. We observe that personal engagement crucially depends on (i) the type of franchise extension (sequel vs. another type) and (ii) the availability of a franchise extension at the time of watching the focal media product. If a sequel is available at the time of watching the focal anime, individuals who watch the focal anime season intensively are more likely to watch the sequel, to finish watching it, and to watch it immediately next than individuals who watch at a slower pace (all three differences are statistically significant at  $p < 0.01$ ). If another type of franchise extension is available at the time of watching the focal anime, individuals who watch the focal anime season intensively are more likely to watch this other type of franchise extension immediately next and to finish watching it (both differences are significant at  $p < 0.01$ ), but are not more likely to watch it than individuals who watch at a slower pace. And lastly, if another type of franchise is not available at the time of watching the focal anime, individuals who watch intensively are less likely to watch the franchise extension once it becomes available than consumers who watch at a slower pace (difference significant at  $p < 0.01$ ).

— Insert Table 3 about here —

In Figure 7, we report statistics related to users' interactive engagement. Note that, out of the three types of UGC on this platform (i.e., forum posts, ratings, and recommendations),

ratings are the dominant form of UGC in terms of user participation: the submission rate is 92.66% for ratings compared to 0.68% for forum posts and 0.18% for recommendations. Further, we find that users who watch an anime season intensively are less likely to post on the discussion forum (difference statistically significant at  $p < 0.01$ ). Conditional on posting on the discussion forum, users who watch an anime season intensively make longer and more negative posts (both differences statistically significant at  $p < 0.01$ ). Further, users who watch an anime season intensively are less likely to rate it, but conditional on rating, they rate it higher (both differences statistically significant at  $p < 0.01$ ). We do not observe significant differences between users who watch intensively and users who watch extensively in their recommendation behaviors.

— Insert Figure 7 about here —

## 4 Models and Estimation

We investigate the relationship between the viewing modus and a consumer’s personal and interactive media franchise engagement. Potential endogeneity of the decision to watch intensively is a concern. To account for it, we simultaneously model an individual’s viewing modus decision and media engagement decisions for the focal anime season allowing for the error terms across the two equations to be correlated (see Heckman 1978, Maddala 1983, Wooldridge 2010).

We start by describing the viewing modus equation.<sup>19</sup> Let  $i = 1, \dots, N$  denote consumers and  $j = 1, \dots, J$  denote animes. Individual  $i$ ’s decision on whether to watch anime  $j$  intensively is given by

$$\begin{aligned}
 B_{ij}^* &= \alpha_i^B + \beta_1^B w_{ij} + \beta_2^B h_{ij} + \delta^B C_{ij}^B + \gamma^B G_j^B + \lambda^B T + \epsilon_{ij}^B \\
 B_{ij} &= \begin{cases} 1 & B_{ij}^* > 0 \\ 0 & \textit{otherwise} \end{cases}, \tag{1}
 \end{aligned}$$

---

<sup>19</sup>Note that the viewing modus equation always includes the same set of variables as described in Equation (1). However, for each personal and each interactive engagement variable, we re-estimate the viewing modus equation together with the engagement equation for each engagement variable allowing for a correlation between the two error terms.

where  $B_{ij}^*$  is the underlying latent variable capturing consumer  $i$ 's utility of watching anime  $j$  intensively. The variable  $B_{ij}$  (whose realizations we observe in the data) equals 1 if  $B_{ij}^*$  is positive and 0 otherwise.  $B_{ij}^*$  is a function of individual-specific random effects  $\alpha_i^B$  following a normal distribution  $N(\bar{\alpha}^B, \sigma_{\alpha^B}^2)$ , a weekend dummy  $w_{ij}$ , a holiday dummy  $h_{ij}$ , control variables  $C_{ij}^B$ , anime-specific variables  $G_j^B$ , time dummies  $T$ , and an error term  $\epsilon^B$  that follows a standard normal distribution.<sup>20</sup> The control variables  $C_{ij}^B$  consist of the popularity rank and the community rating of anime  $j$  with both variables being measured at the time of user  $i$ 's adoption of the focal anime season.<sup>21</sup>  $G_j^B$  contains anime-specific variables, namely, anime  $j$ 's genre dummies, the number of episodes in a season, and the length of each episode in minutes. Note that an anime typically belongs to three to four genres and the genre assignment is done by the platform. And lastly,  $T$  contains calendar year dummies.

Next, we describe how we model a consumer's personal engagement with a media franchise. All three personal engagement variables under study are operationalized as binary indicator variables. Thus consumer  $i$ 's utility from personally engaging with the media franchise is given by

$$y_{ij}^* = \alpha_i + \left( \beta_1 + \beta_2 S_j + \beta_3 A_{ij} + \beta_4 S_j A_{ij} \right) B_{ij} + \kappa_1 S_j + \kappa_2 A_{ij} + \kappa_3 S_j A_{ij} + \delta C_{ij} + \gamma G_j + \lambda T + \epsilon_{ij}$$

$$y_{ij} = \begin{cases} 1 & y_{ij}^* > 0 \\ 0 & \text{otherwise} \end{cases} .$$
(2)

The variable  $y_{ij}$  (whose realizations we observe in the data) equals 1 if  $y_{ij}^*$  is positive and 0 otherwise. The underlying personal engagement utility  $y_{ij}^*$  is a function of individual-specific random effects  $\alpha_i$  following a normal distribution  $N(\bar{\alpha}, \sigma_{\alpha}^2)$  and a dummy variable  $B_{ij}$  indicating whether user  $i$  watched anime  $j$  intensively. Because both the type and the availability of a franchise extension play important roles in precisely pinning down the effects of HiVi (see also

---

<sup>20</sup>The weekend and holiday indicators,  $w_{ij}$  and  $h_{ij}$ , can be interpreted as exclusion variables. We expect users to have more time on weekends and on holidays and thus to be more likely to watch intensively, while these variables should have no/less effect on users' subsequent personal and interactive engagement.

<sup>21</sup>The popularity rank is based on the number of users who adopted the anime. The community rating is the average rating of users who watched the anime. Users can see both variables on the platform.

Section 3.4), we not only estimate a main effect of HiVi, but also interact it with a dummy variable  $S_j$  indicating whether the franchise extension is a sequel and with a dummy variable  $A_{ij}$  indicating whether the franchise extension was available at the time of user  $i$  watching the focal anime season. Furthermore, we account for the main and interaction effects of the sequel dummy  $S_j$  and the availability dummy  $A_{ij}$ .<sup>22</sup> Our control variables  $C_{ij}$  include the popularity rank and community rating of anime  $j$  both measured at the time of user  $i$  watching the focal anime season and, if the franchise extension was not available at the time of user  $i$  watching the focal anime season, the wait time until the franchise became available in days. And lastly,  $G_j$  contains genre dummies for anime  $j$ ,  $T$  contains calendar year dummies, and  $\epsilon_{ij}$  is an error term following a standard normal distribution.

Given that both the viewing modus variable described in Equation (1) and the three personal engagement variables described in Equation (2) are indicator variables, the three models – one for each personal engagement variable – are estimated as bivariate probit models.

And lastly, we describe how we model a consumer’s interactive engagement with a media franchise. As we describe in Section 3.2, we operationalize three UGC incidence variables as binary indicator variables and the remaining five UGC valence, count, and length variables (conditional on UGC incidence) as continuous variables. For the UGC incidence variables (e.g., forum post indicator), consumer  $i$ ’s engagement is modeled as follows:

$$y_{ij}^* = \alpha_i + \beta B_{ij} + \delta C_{ij} + \gamma G_j + \lambda T + \epsilon_{ij}$$

$$y_{ij} = \begin{cases} 1 & y_{ij}^* > 0 \\ 0 & \text{otherwise.} \end{cases} \quad (3a)$$

If the variable capturing interactive media engagement is continuous (e.g., rating valence), consumer  $i$ ’s engagement is modeled as

$$y_{ij}^* = \alpha_i + \beta B_{ij} + \delta C_{ij} + \gamma G_j + \lambda T + \epsilon_{ij}. \quad (3b)$$

$\alpha_i$  is an individual-specific random effect following a normal distribution  $N(\bar{\alpha}, \sigma_\alpha^2)$  and  $B_{ij}$  is

---

<sup>22</sup>Note that for the personal engagement form of whether to watch a franchise extension *immediately next* after watching the focal anime, we condition on the availability of a franchise extension at the time of watching the focal anime. Thus, for that equation, we are not able to estimate the effects of availability.

a dummy variable indicating whether user  $i$  watched anime  $j$  intensively.  $C_{ij}$  contains control variables including the popularity rank, the average community rating, and the number of previous forum posts about, ratings of or recommendations for anime  $j$  at the time of individual  $i$ 's adoption of the focal anime season. For dependent variables related to forum posts only, we also control for whether consumer  $i$  has ever published a forum post and the time since the last forum post on anime  $j$  published by anyone.  $G_j$  contains anime-specific variables such as the number of episodes in a season and genre dummies, and  $T$  contains calendar year dummies. Lastly,  $\epsilon_{ij}$  is the error term following a standard normal distribution.

If the interactive media engagement variable is binary as described in Equation (3a), we jointly estimate the viewing modus equation and the interactive media engagement equation using a bivariate probit model with correlated errors. If the interactive media engagement variable is continuous as described in Equation (3b), we jointly estimate the viewing modus equation and the interactive media engagement equation using a probit and a linear model with correlated errors.

## 5 Results

### 5.1 Viewing Modus Decision

We start by discussing the results for consumers' viewing modus decisions. The lower halves of Tables 4 and 5 show the results from the model parts capturing the decision to watch intensively. Across the eleven sets of results shown in Tables 4 and 5, the coefficient estimates have the expected signs and most of them are significant: the coefficients for the weekend and holiday dummies are, as expected, positive. The lower the popularity rank of the focal anime season (i.e., the better the rank), the more likely it is that an individual watches it intensively. Higher rated anime series with more and longer episodes also increase the probability of HiVi. We also find evidence for a significant amount of unobserved heterogeneity across users. Lastly, six out of eleven correlations between the viewing modus and engagement decisions are statistically

significant with some correlations being positive and some being negative.

— Insert Tables 4 and 5 about here —

## 5.2 Personal Engagement

The top half of Table 4 shows the parameter estimates from the model parts describing consumers' personal engagement actions. Column (i) describes an individual's decision of whether to watch a franchise extension (at any point in time). We find the main effect of HiVi as well as all four interaction effects (three two-way interactions and one three-way interaction) to be statistically significant, suggesting that the effect of HiVi critically depends on the type of franchise extension (sequel versus other type) and its availability at the time of watching the focal media product. To facilitate interpretation of the effects of HiVi in each of the four scenarios (sequel/available, sequel/not available, other type/available, other type/not available), we separately show the effects of HiVi (taking all main and interaction effects of the binge dummy into account) for each scenario in column (i) in Table 6.<sup>23</sup>

— Insert Table 6 about here —

When a franchise extension is available, we find that watching the focal media product intensively (compared to watching it at a slower pace) significantly increases the likelihood of adopting a sequel, while it significantly decreases the likelihood of adopting other types of franchise extensions. This finding is consistent with consumers experiencing a stronger and more seamless flow effect by watching a sequel compared to watching other types of franchise extensions. In the case of a sequel, the stronger flow created by watching intensively overcomes the satiation effect and therefore leads to a positive net effect on adopting this specific type of franchise extension. For other types of franchise extensions, since the flow is not as strong due to the weaker connection to the focal media product, the satiation effect dominates resulting in a negative net effect on adoption.

---

<sup>23</sup>For example, we calculate the effect of HiVi for the sequel/available scenario as follows:  $0.069 = -0.142 + 0.036 + 0.030 + 0.145$ . We use the Delta method to calculate the standard errors.

When a franchise extension is not available at the time of watching the focal media product, we find that watching intensively (compared to watching at a slower pace) significantly decreases the adoption probability for both sequels and other types of franchise extensions (once the media franchise becomes available). Given the separation in time between watching the focal media product and the possibility of adopting its franchise extension due to its initial unavailability, the flow effect is not strong in this situation. As a result, the net effect of HiVi is mainly driven by the satiation. This is why we find the adoption probabilities of both sequels and other types of franchise extensions to decrease when they are not available at the time of watching the focal anime season.

We further examine whether HiVi affects a consumer's probability of finishing to watch the franchise extension (conditional on starting to watch a franchise extension) in column (ii) of Table 4. Again, we calculate the effect of HiVi (taking all main and interaction effects into account) for each of the four scenarios separately and show them in column (ii) in Table 6. We find that, after starting to watch a franchise extension, users who watch the focal media product intensively are significantly more likely to finish watching the franchise extension than users who watch it at a slower pace in all four scenarios. These results suggest that, once consumers overcome their satiation (with the media franchise) and start watching a franchise extension, the positive flow effect dominates which increases the probability of finishing to watch the franchise extension.

Lastly, we examine how viewing modus affects the more immediate media watching behavior. In column (iii) of Table 4, we pin down how HiVi affects a consumer's probability of watching a franchise extension (compared to an unrelated media product) immediately next (conditional on it being available at the time of watching the focal media product). We find that individuals who watch a focal anime season intensively are more likely to watch a franchise extension immediately next than individuals who watch at a slower pace, and that this effect is stronger when the franchise extension is a sequel (versus another type – see column (iii) in Table 6). This result again speaks to the consumers' tendency to continue the flow created by watching the focal media product intensively. A natural way to do so is to watch its franchise extensions

if one is available. Relative to other types of franchise extensions, sequels benefit more from the HiVi effect because of the stronger flow they create.

To summarize, our results for personal engagement show that HiVi only increases a consumer’s probability of watching a franchise extension (at any point in time in the future) if that franchise extension is a sequel *and* available at the time of watching the focal media product. Otherwise, HiVi decreases the adoption probability of a franchise extension. However, conditional on starting to watch a franchise extension, HiVi increases the probability that a consumer finishes to watch it in all four scenarios. Further, HiVi also increases the probability that a consumer watches a franchise extension immediately next after watching the focal media product. And lastly, we would like to stress that our results regarding both personal and interactive engagement are robust to alternative operationalizations of HiVi (shorter and longer average daily watch times of 2 and 4 hours) as shown in Web Appendix B.

### 5.3 Interactive Engagement

Next, we discuss the results for interactive engagement shown in the upper half of Table 5. Columns (i) to (iv) in Table 5 display the coefficients for estimations related to forum posts. Our results in columns (i) and (iii) indicate that HiVi (compared to LoVi) does not significantly affect a user’s probability of making forum posts – neither the incidence nor the number of forum posts. Whether a user contributes to the discussion forum and the number of her contributions rather appear to be largely driven by unobserved consumer heterogeneity. Conditional on contributing to the discussion forum, if an individual watches intensively, she makes more negative but longer posts (columns (ii) and (iv)). However, it is important to note that this negative effect on valence does *not* necessarily mean that consumers who watch intensively have a more negative opinion of the focal media product as a consequence of the viewing modus. As mentioned before, discussion threads cover a wide range of topics related to the focal anime season, including new season release dates, voice cast decisions, story lines, specific characters, awards, and anime adaptations. It is possible that, if an individual watches intensively, she likes

the focal media product more, but makes a more negative post in a thread on the discussion forum, for example, about the wait time until the next season becomes available.

Columns (vii) and (viii) in Table 5 show the results for recommendations – another form of verbal UGC. Recall that recommendations on this platform exhibit the following pattern: “If you like anime A, you will like anime B because of XYZ.” In that sense, individuals give a recommendation for which two animes are *similar*, but not necessarily an endorsement that either of these two animes is particularly good. Providing such a recommendation is likely to be driven by a consumer’s higher interest level in an anime. We find that consumers who watch intensively are significantly more likely to write a recommendation for the focal media product than consumers who watch at a slower pace, but conditional on submitting a recommendation, the former group does not write more recommendations than the latter group. Here, it is also important to note that the recommendation count is very small in our estimation sample since only a very small fraction of users make any recommendations and an even smaller fraction of users makes more than one recommendation.

Ratings are different from the two previously mentioned forms of UGC in that they are numerical and in that a higher rating clearly indicates a more favorable opinion towards the rated anime. Furthermore, while ratings are publicly visible to everybody like the two other forms of UGC, they are recorded by a user on her watch list and help her remember her preference for or liking of a particular anime. This partly explains why ratings are the dominant form of UGC in terms of user participation on this platform. Our results in columns (v) and (vi) in Table 5 show that, if an individual watches intensively, she is significantly less likely to rate the focal media product, but if she does rate it, she gives it a more positive rating than an individual who watches at a slower pace.

To summarize, our results show that forum post incidence and frequency are rather driven by unobserved consumer heterogeneity than HiVi. We also find that HiVi increases the probability that an individual writes a recommendation for the focal media product. And lastly, we find that consumers are less likely to rate an anime if they watch intensively, but conditional on rating it, they give it a more positive rating.

Given that consumers who watch intensively are less likely to rate animes, we interpret our results as providing partial support for HiVi having a negative effect on the amount of UGC produced. We acknowledge that HiVi increases the probability of writing a recommendation. However, ratings are a far more frequent form of interactive engagement on this platform (and on most UGC platforms in general). We believe the negative effect of HiVi on the rating submission can be explained by the inclination of consumers who watch intensively to stay in the flow and to avoid any activity that distracts from or interrupts the watching, which is also consistent with the avoidance tendency of bingeing individuals towards advertisements documented in Schweidel and Moe (2016).

Furthermore, we believe that our results provide some evidence that HiVi increases consumers' liking of an anime. This is because individuals who watch intensively rate the focal anime higher. This effect is consistent with previous research which suggests that bingeing induces loyalty and fandom-like behavior (Devasagayam 2014, Jenner 2015).

## 6 Heterogeneity

In this section, we explore the extent of heterogeneity in our results with respect to five consumer characteristics: geography, age, gender, usage, and experience.<sup>24</sup> We explore three manifestations of heterogeneity: (i) in the viewing modus decision, (ii) in the baseline probability to engage, and (iii) in the effect of viewing modus.

We start by exploring heterogeneity in the viewing modus decision.<sup>25</sup> We find that consumers outside of North America are less likely to watch intensively than consumers in North America. Older (above 25 years), more experienced consumers, and consumers with higher recent usage are also less likely to watch intensively than younger, less experienced consumers,

---

<sup>24</sup>We operationalize all heterogeneity variables as dummy variables. For experience, we conduct a median-split and operationalize experience as a high-experience dummy variable. Similarly, for usage, we conduct a 3rd quartile split and operationalize usage as a high-usage dummy variable. We use the 3rd quartile as the split cutoff for usage because the median is 0. Geography and gender vary across individuals; age, usage, and experience vary across individuals and time.

<sup>25</sup>Coefficient estimates for the heterogeneity variables (quantifying the effects of the heterogeneity variables on consumers' decision to watch intensively) are shown in the lower halves of Tables C-1 to C-10 in Web Appendix C.

and consumers with no recent usage, respectively.

Next, we describe heterogeneity in both the baseline probability to engage and in the effects of viewing modus on consumers’ personal and interactive engagement. A summary of the results is shown in Table 7. Note that the table contains the results from a large number separate regressions – one for each of the five sources of heterogeneity and each dependent variable. The complete regression results with all coefficient estimates for all regressions can be found in Web Appendix C. Further note that, since we are interested in the extent of heterogeneity, we show the *differential effects* in Table 7, i.e., the estimates displayed in Table 7 indicate *by how much* an effect is *different* from the baseline and whether this difference is statistically significant. *Intuitively speaking, significant effects in Table 7 mean that there is heterogeneity and insignificant effects mean that there is no heterogeneity.*<sup>26</sup> And lastly, in Table 7, we show both how the baseline probabilities to engage vary with consumer characteristics – these effects are denoted by, for example, “Differential Effect of Europe” or “Differential Effect of Being Female” – and how the effects of viewing modus vary with consumer characteristics – these effects are denoted by, for example, “Differential Effect of HiVi in Europe” or Differential Effect of HiVi for Females.”

In the following, we use a few examples to illustrate how the estimates in Table 7 should be interpreted. For example, the baseline for the regressions exploring geographic heterogeneity is North America (see 2nd line in Table 7). The differential effect of HiVi in Europe (as compared to North America) for “Sequel & Available” is  $-0.021$  and statistically insignificant (see column (i) in Table 7).<sup>27</sup> This result shows the effect of HiVi on whether consumers watch a franchise extension in case of “Sequel & Available” is the same for consumers in Europe and North America. To give a second example, the differential effect of watching intensively in Asia (as compared to North America) on forum post incidence is  $0.189$  and significant at  $p < 0.05$

---

<sup>26</sup>We acknowledge that, strictly speaking, a statistically insignificant differential effect means that we cannot reject the null hypothesis of no heterogeneous effect and a statistically significant differential effect means that we can reject the null hypothesis of no heterogeneous effect.

<sup>27</sup>The differential effect of bingeing in Europe for “Sequel & Available” was calculated as follows using the coefficient estimates from column (i) in Table C-1 in Web Appendix C:  $\text{Europe} \times \text{HiVi} + \text{Europe} \times \text{HiVi} \times \text{Sequel} + \text{Europe} \times \text{HiVi} \times \text{Available} + \text{Europe} \times \text{HiVi} \times \text{Sequel} \times \text{Available} = 0.005 + (-0.093) + 0.017 + 0.050 = -0.021$ .

(see column (iv) in Table 7).<sup>28</sup> This implies that Asian consumers who watch intensively are significantly more likely to post on the discussion forum than North American consumers who watch intensively. And lastly, we also show the differential effects of the heterogeneity variables on the baseline engagement probabilities. For example, the “Differential Effect of Europe” on watching a franchise extension is 0.126 and significant at  $p < 0.001$  (see column (i) in Table 7).<sup>29</sup> This means that consumers in Europe are significantly more likely to watch a franchise extension than consumers in North America.

— Insert Table 7 about here —

Our results suggest a limited amount of heterogeneity in the baseline probabilities of engaging with a media franchise. We find that consumers outside of North America are more likely to personally engage, but less likely to interactively engage with a media franchise than consumers in North America. Female consumers are more likely to finish watching a franchise extension, to submit ratings, and to publish posts on the discussion forum than male consumers. However, the length of forum posts and valence of ratings submitted by women is lower than the length of forum posts and valence of ratings submitted by men. Older consumers, in general, are less likely to interactively engage with a media franchise than younger consumers, as indicated by their lower participation in all three forms of UGC. Further, we find very little to no heterogeneity in the engagement probabilities related to experience and recent usage.

Lastly, we discuss the amount of heterogeneity in the effects of viewing modus. Regarding personal engagement, consumers outside of North America who watch intensively are generally more likely to watch a franchise extension immediately next than consumers in North America who watch intensively (see column (iii) in Table 7). With regard to interactive engagement, consumers in Europe and Oceania who watch intensively write more forum posts than consumers in North America who watch intensively. Consumers in South America and Asia who watch intensively submit fewer ratings and worse ratings, respectively, than consumers in North

---

<sup>28</sup>The differential effect of HiVi in Asia on forum post incidence equals the coefficient estimate for  $\text{Asia} \times \text{HiVi}$  in column (i) in Table C-2 in Web Appendix C.

<sup>29</sup>The differential effect of Europe on watching a franchise extension equals the coefficient estimate for the Europe dummy in column (i) in Table C-1 in Web Appendix C.

America who watch intensively. We only find two heterogeneous effects of HiVi related to age: the effect of HiVi on watching a franchise that is neither a sequel nor available is smaller for people older than 20 years old than younger people and the effect of HiVi on watching a franchise that is not sequel immediately next is larger for the age group of 20 to 25 years than for younger consumers. Regarding our two behavioral segmentation criteria of experience and recent usage, our results show that consumers with a lot of experience who watch intensively are less likely to finish a franchise extension (that is unavailable and of other type) than consumers with little experience who watch intensively. Further, we find that the effect of HiVi on interactive engagement varies with experience: consumers with more experience who watch intensively write more forum posts and more recommendations but give worse ratings than their less experienced counterparts. And lastly, we find that consumers with high recent usage who watch intensively write more recommendations than consumers with no recent usage who watch intensively.

To summarize, geographic heterogeneity is mostly captured by different behaviors of consumers in and outside of North America: consumers outside of North America are less likely to watch intensively, more likely to engage personally, and less likely to engage interactively than consumers in North America. Further, if consumers outside of North America watch intensively, they are more likely to watch a franchise extension immediately next than consumers from North America who watch intensively. We find a limited amount of heterogeneity related to age and gender: older consumers are less likely to watch intensively and produce UGC related to a media franchise than younger consumers. Women are more likely to write forum posts and submit ratings, but these forum posts are shorter and ratings are worse than those written and submitted by men. Among our two behavioral segmentation criteria of experience and recent usage, our results indicate that more experienced consumers and consumers with higher recent usage are less likely to watch intensively than less experienced consumers and consumers with no recent usage. Lastly, we find that the effects of HiVi on interactive engagement vary with experience and usage: more experienced consumers and consumers with higher recent usage who watch intensively tend to generate more forum posts and/or recommendations related to

a media franchise than less experienced consumers and consumers with no recent usage who watch intensively.

## 7 Limitations and Future Research

There are several limitations to our research. First, a media franchise can also include merchandising items that are available for purchase, such as posters, coffee mugs, toys, and trading card games. In our data, we do not observe purchases of such ancillary products. It is left for future research to investigate whether the viewing modus affects such purchases. Second, even though we provide evidence for the validity of our data, measurement error in our HiVi variable due to its self-reported nature remains a potential concern. It is well-known that measurement error in an independent variable leads to attenuation bias, i.e. a bias of the coefficient towards zero. Thus our results should be interpreted as a lower bound of the effects of HiVi.

Third, some TV shows or movies have a higher probability of being watched intensively than others due to their creative content, which we do not consider in our model. It is left for future research to study whether and how different content characteristics make a show more or less suitable for an intensive viewing modus. And lastly, viewing modus may differ significantly depending on the methods or channels of watching such as online streaming websites, streaming platforms, DVDs, or piracy websites. An interesting direction for future research is to explore how these different channels should design and deploy user interfaces, advertising methods, and sequential watching strategies to influence the viewing modus.

## 8 Conclusion

With the introduction of high-speed Internet during the last 15 years, HiVi has become very common among TV viewers. An open empirical question is whether the viewing modus has implications for user engagement compared to the traditional, linear way of watching TV. In this paper, using novel data coming from an online anime platform containing information on

individual users' adoptions of different animes and their user-generated content, we examine the relationship between HiVi and consumers' engagement with a media franchise as related to user-generated content and the adoption of franchise extensions. Our paper thus adds to the small but rapidly growing body of literature on consumers' digital media consumption as well as on the online streaming industry. To the best of our knowledge, our paper is the first systematic empirical examination of the effects of viewing modus on user engagement with a media franchise.

Our results show that the effect of HiVi on personal engagement crucially depends on both the type and the availability of franchise extensions at the time of watching the focal media product. If the franchise extension is available, HiVi increases the probability that a user watches the next season, while it has the opposite effect for other franchise extensions. If the franchise extension is not available, HiVi decreases the adoption probability for both sequels and other types of franchise extensions. However, conditional on starting to watch a franchise extension, watching intensively increases the probability that a consumer finishes to watch it in all four scenarios. We also find that HiVi increases the probability that a consumer watches a franchise extension immediately after watching the focal media product. We believe these effects are driven by the balance between the flow and the satiation, two forces created by HiVi but operating in opposite directions. Regarding interactive engagement, our results suggest HiVi decreases the submission of ratings, the most dominant form of UGC on the platform, providing partial support for the avoidance tendency of binge-watchers proposed and documented in previous literature.

Our results offer the following important managerial implications for TV channels and online streaming platforms. First, HiVi can boost viewership of subsequent seasons (sequels). However, the availability of the subsequent season plays a crucial role. Media content providers have started to recognize this by making prior seasons available (for intensive viewing) shortly before the release of the next season. Figure 8 shows several examples from Netflix.

— Insert Figure 8 about here —

Second, HiVi does not boost viewership of all franchise extensions. Which franchise extensions benefit from a prior season that is available for intensive viewing depends on whether the franchise extension helps to continue the flow viewers experience when watching the prior season intensively. Franchise extensions that differ significantly in story lines and/or main characters may not attract viewers who watched the prior season intensively. The general lackluster performance of spin-offs speaks to the importance of staying close to the successful original series when developing franchised extensions.<sup>30</sup>

Third, online streaming platforms such as Netflix have been aggressive in expanding their services beyond the home country. Our study provides first empirical evidence regarding the similarities and differences in consumers' media consumption and engagement behaviors across five continents. Specifically, we find that the effects of HiVi are present and robust across the different regions, with a stronger effect on personal engagement for consumers outside of North America. These findings provide valuable information that helps streaming providers decide to what extent their content strategy in general and content release timing strategy in particular should be customized to accommodate local consumers' preferences.

**Table 4: Results - Personal Engagement**

Note that all three variables “High Intensity Viewing,” “Sequel,” and “Availability” are dummy variables. The model in column (ii) is estimated using user-anime observations for which the user decided to watch a franchise extension, i.e. conditional on watching (any type of) franchise extension. The model in column (iii) is estimated using user-anime observations for which (at least) one franchise is available at the time of watching the focal anime, i.e. conditional on a franchise being available.

	Whether Franchise was		
	Watched (i)	Finished (ii)	Watched Next (iii)

**Table 5: Results - Interactive Engagement**

Note that the variable “High Intensity Viewing” is a dummy variable.

The models in column (ii), (iii), and (iv) are estimated using user-anime observations for which the user made (at least) one forum post, i.e. conditional on a forum post. The model in column (vi) is estimated using user-anime observations which the user rated, i.e. conditional on a rating. The model in column (viii) is estimated using user-anime observations for which the user wrote a recommendation, i.e. conditional on a recommendation.

<sup>a</sup> High Intensity Viewing

# Web Appendix A: Definitions

**Table A-1: Definitions of Engagement**

Paper	Definition	Personal Engagement	Interactive Engagement
Algesheimer et al. (2005)	Define “brand community engagement” as “a consumer’s intrinsic motivation to interact and cooperate with community members.”		✓
Patterson et al. (2006)	Propose four specific customer engagement (CE) components, including (a) absorption: the level of customer concentration on a focal engagement object, such as a brand/organization; (b) dedication: a customer’s sense of belonging to the organization/brand; (c) vigor: a customer’s level of energy and mental resilience in interacting with a focal engagement object; and (d) interaction: the two-way communications between a focal engagement subject and object.	✓	
Wagner and Majchrzak (2006)	Intensity of customer participation with both representatives of the organization and with other customers in a collaborative knowledge exchange process		✓
Unit (2007)	Report that 79% of consumers defined engagement as recommending, and 64% of consumers defined it as frequent purchase	✓	✓
Nambisan and Nambisan (2008)	Customer experience in virtual CE is made up of four components: pragmatic experience, sociability experience, usability experience and hedonic experience.	✓	✓
Bowden (2009)	A psychological process that models the underlying mechanisms by which customer loyalty forms for new customers of a service brand as well as the mechanisms by which loyalty may be maintained for repeat purchase customers of a service brand	✓	
Calder et al. (2009)	Identified two different kinds of engagement. One kind, personal engagement, is when users seek stimulation and inspiration from the site, they want to use the site to facilitate their interactions with other people, they feel the site affirms their self-worth, they get a sense of intrinsic enjoyment in using the site itself... The second kind, social-interactive engagement, is weighted more towards experiences that are more unique to the web, such as participating in discussions and socializing with others through a site.	✓	✓
Higgins and Scholer (2009)	A state of being involved, occupied, fully absorbed or engrossed in something (i.e., sustained attention), generating the consequences of a particular attraction or repulsion force.	✓	
Kumar et al. (2010)	Identify 4 components: 1) customer purchasing behavior, whether it be repeat purchases or additional purchases through up-selling and cross-selling; 2) customer referral behavior as it relates to the acquisition of new customers through a firm initiated and incentivized formal referral programs (extrinsically motivated); 3) customer influencer behavior through customers’ influence on other acquired customers as well as on prospects (e.g., word-of-mouth activity that persuades and converts prospects to customers, minimizes buyer remorse to reduce defections, encourages increased share-of-wallet of existing customers; usually intrinsically motivated); 4) customer knowledge behavior via feedback provided to the firm for ideas for innovations and improvements, and contributing to knowledge development (extrinsically or intrinsically motivated).	✓	✓
Van Doorn et al. (2010)	Customers’ behavioral manifestation toward a brand or firm, beyond purchase, resulting from motivational drivers such as word-of- mouth activity, recommendations, helping other customers, blogging, writing reviews.		✓
Brodie et al. (2011)	CE is a psychological state that occurs by virtue of interactive, co-creative customer experiences with a focal agent/object		✓
Vivek et al. (2012)	CE is the intensity of an individual’s participation in and connection with an organization’s offerings or organizational activities, which either the customer or the organization initiates.	✓	

**Table A-2: Definitions of Binge-Watching**

Paper	Definition
Schweidel and Moe (2016); Rajaram et al. (2018)	Consumption of multiple episodes of a television series in a short period of time
MarketCast (2013); Devasagayam (2014); Pena (2015); Shim and Kim (2018); Godinho de Matos and Ferreira (2018)	Respondents’ perception of what is considered binge-watching without defining a specific amount
Netflix (2013); Sung et al. (2015); Ahmed (2017); Walton-Pattison et al. (2018)	Watching of at least two episodes in one sitting
Devasagayam (2014); Pena (2015)	Watching with the purpose of finishing a whole season in a short period of time
TiVo (2015)	Watching 3 or more episodes in one day
Trouleau et al. (2016)	Hyperbinge (3 episode or more) vs binge (2 episode) in one sitting
Wheeler (2015); Lu et al. (2017)	Many episodes in a single day
Zhang et al. (2013, 2015); Pittman and Sheehan (2015); Flayelle et al. (2017); Shim and Kim (2018)	Multiple episodes in one sitting

# Web Appendix B: Results with Alternative Operationalizations of Binge-Watching

**Table B-1: Personal Engagement - 2 Hours**

Note that all three variables “High Intensity Viewing,” “Sequel,” and “Availability” are dummy variables. The model in column (ii) is estimated using user-anime observations for which the user decided to watch a franchise extension, i.e. conditional on watching (any type of) franchise extension. The model in column (iii) is estimated using user-anime observations for which (at least) one franchise is available at the time of watching the focal anime, i.e. conditional on a franchise being available.
