Abstract

Flexible labor markets require geographically mobile workers to be efficient. Otherwise firms can take advantage of the immobility of workers and extract monopsony rents. In cultures with strong family ties, moving away from home is costly. Thus, individuals with strong family ties rationally choose regulated labor markets to avoid moving and limiting the monopsony power of firms, even though regulation generates lower employment and income. Empirically, we do find that individuals who inherit stronger family ties are less mobile, have lower wages, are less often employed and support more stringent labor market regulations. We find positive correlations between labor market rigidities at the beginning of the twenty first century and family values prevailing before World War II, and between family structures in the Middle Ages and current desire for labor market regulation. Both results suggest that labor market regulations have deep cultural roots.

1 Introduction

Labor market institutions differ across countries and stringent labor market regulations persist despite being economically inefficient.¹ In the present paper we endogeneize the choice of labor market institutions as a function of differences in cultural values, proposing

*We thank Murat Iyigun and seminar participants at Bocconi University, Brown University, Harvard University, the Kaler meeting at UCLA, IZA, IIES (Stockholm), the London School of Economics, New York University, Princeton University, the Terry College of Business, UC Berkeley Haas School of Business, University of Mannheim, University of Southern California, the AEA Meetings (Denver), the CEPR Conference on Culture and Institutions in Milan and the Politics, Information and the Macroeconomy conference in Barcelona for helpful comments.

¹Most economists, although with varying emphasis, for example would argue that these regulations are at least in part responsible for the high European unemployment from the eighties onward. For a balanced view see Blanchard and Wolfers (2000).

an interpretation based upon the complementarity between the strength of family ties and the stringency of labor market regulation.² Flexible labor markets require that individuals move geographically in order to maximize their opportunities, find the best match with a firm and get the best paid job. This is efficient when mobility is painless. However, in certain cultures, staying close to the family is important and the mobility required by a free labor market is painful. With unregulated labor markets, local firms would have a monopsonistic power over immobile workers and would pay their reservation wage which could be below their productivity. Thus workers with strong family ties would favor labor regulation to counteract this power. This can lead to two different equilibria. One is *laissez-faire*, with high mobility and unregulated labor markets; this occurs when family ties are weak. When family ties are strong, there is another equilibrium with labor market rigidity comprising minimum wage and firing restrictions. Given the cultural value placed on family ties, labor market regulation is preferable to *laissez-faire*. Even though *laissez-faire* produces higher income per capita it rarefies family relations. If family ties are sufficiently strong this relaxation of family relationships can reduce individual utility so much that welfare can be higher with a regulated labor market.³

An innovative feature of our model is that individuals can choose the degree of family ties, or to be more realistic, they can educate their children in a certain way. This implies a two way effect between family ties and labor market regulation. An inherited culture of strong family ties leads to a preference for labor market rigidities, but the latter in turn makes it optimal to teach and adopt strong family ties. Thus economic incentives explain the evolution of cultural values and the other way around⁴.

²The most common explanations for the persistence of rigidities in the labor market rely upon various versions of the insider-outsider model (Lindbeck and Snower (1989), Blanchard and Giavazzi (2003) and Saint-Paul (2000)), in which unionized "inside" workers want to preserve their rents and want to avoid competition from the outsiders. However, this interpretation does not explain why insiders are more powerful in some countries than in others. In addition, the logic of this model implies that the "outsiders" should oppose labor regulations, but in reality this is not the case. In fact those that could be considered outsiders favor extending the coverage to themselves as well rather than liberalizing the labor market.

³Our model does not have home production, but with strong family ties hours not spent at work can be devoted to work at home. Thus adding home production would reinforce the result of the model because lower work in the market would be less costly in strong family ties societies.

⁴Hassler et al. (2005) also look at the interaction between labor market institutions (in particular unemployment insurance) and geographical mobility, finding a negative relationship between the two. In their theoretical interpretation differences in the propensity to move are given and are not a function of a particular cultural trait, also the paper does not provide an empirical test of their theory.

In our empirical analysis we study the interaction between family ties, labor market institutions and outcomes. We motivate our analysis by documenting a strong correlation at the country level between family ties (measured using a variety of subjective indicators on family values and objective measures of family arrangements) and labor market regulations. Our main empirical contribution relies however upon micro evidence. In particular, to mitigate problems of omitted variables and reverse causality, we rely on evidence from second generation immigrants in the US.⁵ We show that second generation immigrants coming from familistic societies are less mobile, face a wage and employment penalty and also ask for more government regulation of wages and job security. We also show that the strength of family values inherited from the countries of origin before World War II is positively correlated with the stringency of labor market regulation in the countries of origin at the beginning of the 21st century. Using regional variation in medieval family structures, we also document a correlation between desire for regulation today and the structure of the family dating back at least to the Middle Ages. Overall our evidence supports the idea that the relationship at the country level between actual regulation and family values goes through an individual desire for regulation influenced by transmission of cultural values.

The present paper is at the intersection of three strands of the literature. One is the vast area of research on labor market institutions and labor market performance. We provide a different, but however complementary, analysis to the seminal insider outsider model of Saint-Paul (2000, 2002) on employment protection and minimum wage.⁶ The second is the one referred to as cultural economics. This literature has investigated the importance of cultural traits in the determination of economic outcomes,⁷ the transmission of cultural values,⁸ and only recently the interaction between cultural values and economic

⁵Cultural values are relatively slow to evolve, as a vast literature on the behavior of immigrants to other countries, mainly the US, shows. See for instance Alesina and Giuliano (2010), Algan and Cahuc (2005), Fernandez and Fogli (2006, 2009), Giuliano (2007), Guiso et al. (2006), Luttmer and Singhal (2009) amongst many others.

⁶See the recent surveys of Eichhorst et al. (2008) and Freeman (2008).

⁷See Carroll et al. (1994), Guiso et al., (2006, 2009), Tabellini (2008a), Algan and Cahuc (2010), Fernandez and Fogli (2007), Alesina and Giuliano (2010, 2011), Giavazzi et al. (2009), Giuliano (2007).

⁸See Bisin and Verdier (2000, 2001). Their model has been applied to the transmission of religious beliefs (Bisin and Verdier, 2000, and Bisin et al., 2004), of education (Patacchini and Zenou, 2006), of ethnic identity (Bisin et al. 2006), of moral values (Tabellini, 2008b) and the transmission of priors about the trustworthiness of others (Guiso et al. 2008).

institutions.⁹ We contribute to this literature by looking at the interplay and coevolution of labor market institutions and a specific cultural trait of a society, the strength of family ties. In addition, we look at the determinants of different values regarding the family by tracking their origin to the existence of different forms of family arrangements that go back to at least the Middle Ages.¹⁰ The third strand of literature stresses the complementarity between investment in local social ties, including friends and family, and geographical immobility.¹¹

The paper is organized as follows. The next section presents the model. Section 3 documents cross country correlations between family values and the regulation of labor. Section 4 looks at economic outcomes and attitudes of second generation immigrants. Section 5 further documents the issue of persistence and Section 6 concludes.

2 The model

2.1 The setup

There are two goods: labor and a numeraire good produced with labor and a continuum of individuals of mass one. Individuals are uniformly located on the $[0, 1]$ line. They are identical, risk neutral and have no preference for leisure: their utility is equal to the sum

⁹Related to the influence of culture on regulation, Algan and Cahuc (2010) investigate the role of civic virtue on labor market institutions. They show that unemployment benefits are higher in countries displaying higher level of civicness since the degree of moral hazard associated with the use of government benefits is dampened in those countries. On the link from regulation and institutions to culture, Alesina and Angeletos (2005), Alesina, Cozzi and Manotovan (2009), Alesina and Fuchs-Schündeln (2007), Aghion et al. (2011) and Aghion et al. (2010) show that regulation can shape beliefs like the demand for redistribution or beliefs in cooperation. Tabellini (2008b) extends the cultural transmission framework of Bisin and Verdier (2001), allowing the interaction of cultural norms with institutions.

¹⁰Alesina and Giuliano (2010) and Algan and Cahuc (2007) show that differences in family culture could help explain heterogeneity in labor market participation (especially for women and young adult).

¹¹Glaeser, Laibson and Sacerdote (2002) argue that individuals who perceive themselves as being strongly attached to a village, a township or a region, may invest in local social capital, because the returns from these local ties are high while, on the other hand, strong local social capital raises the cost of mobility and in turn reduces incentives to move. Spilimbergo and Ubeda (2004a) show that interactions between social ties and moving decisions can explain the different behaviors of workers in different groups, regions, or countries in an endogenous way by showing the existence of multiple equilibria. Glaeser and Redlick (2008) show that it is possible that an area can get caught in a bad equilibrium where the prospect of out-migration reduces social capital investment and a lack of social capital investment makes out-migration more appealing. David, Janiak and Wasmer (2009) build a model that can include two different equilibria: strong local social capital and low mobility vs. low social capital and high propensity to move.

of their consumption and a term that represents the valuation of family ties to be defined below. The timing is as follows:

1. At birth, every individual is located on the $[0, 1]$ line, on a point where her parents live. Then, individuals choose family values which can be either with strong family ties or with low family ties. The choice of family values is irreversible. In reality family values are "chosen" by parents and transmitted to children. However for the sake of simplicity we collapse the model to a static case without intergenerational transmission of values. Below we also make some progress toward extending our model in a dynamic direction.

The share of individuals with strong family ties is $\sigma \in [0, 1]$. Strong family ties yield an utility $\Delta(\sigma) > 0$, if an individual lives in the same location as her parents, and a disutility $-\Delta(\sigma)$ if he/she lives elsewhere. An individual with weak family ties is indifferent between living in his location of birth or elsewhere, thus $\Delta = 0$ for any σ . We assume $\Delta'(\sigma) \geq 0$. This assumption is very plausible for a variety of reasons. First, social norms are generally more influential when they are more spread around. Living in a community where most people have strong family ties create a strong social norm to which one feels an incentive to conform. In addition, when the share of the population with strong family ties is larger, individuals with weak family ties and those who do not live in the neighborhood of their parents have less opportunities to have social interactions. This may imply that the relative value of strong family ties compared to weak family ties (which is normalized to zero) increases with the share of individuals with strong family ties. It is worth stressing that the assumption that the valuation of family ties depends on the share of individuals with strong family ties is innocuous for our main results. In particular we get multiple equilibria in absence of this assumption when $\Delta'(\sigma) = 0$, as it will become clear below. But we start from the more general model in this section. Also note the difference between the mobility costs associated with family ties and those associated with simple transaction costs of moving. The latter are not a choice variable and depend on the technology of transportation. Besides they are in general not decreasing with the number of people who move; and can even increase in case of congestion.

2. With majority rule individuals vote on labor market regulation. By assumption there are two possible types of labor market policies: either labor market flexibility (i.e. *laissez-faire* on the labor market), or regulation of wages and employment based upon

two instruments, a minimum wage and job protection. These two instruments (described in more detail below) are necessary and sufficient to ensure that the market equilibrium is Pareto efficient when there are mobility costs.

3. Firms offer labor contracts. When a worker is hired in his initial location, his productivity y is drawn from the uniform distribution on the interval $[0, 1]$. Every worker can find a job with productivity 1 in a place different from his initial location. Job protection constrains firms to keep all employees whose productivity is above a threshold value denoted by $R \in [0, 1]$. Job protection entails deadweight losses $c \in [0, 1)$, that is the production of a worker who draws the productivity y is equal to $y - c$, instead of y .¹² In each location, there is a single firm that offers labor contracts. In this setup, workers are paid at their reservation wage, which can be lower than their productivity if there are mobility costs.¹³ When there is a minimum wage, workers can be either employed and paid the minimum wage, denoted by w , or unemployed. They are unemployed if their productivity y is below the reservation productivity R of the firm.

The nature of these assumptions should be clear. A worker with weak family ties would always manage to find a job with productivity $y = 1$ since he bears no costs of mobility. A worker with strong family ties has a moving cost of $2\Delta(\sigma)$. Without labor market regulation, workers with strong family ties face the monopsony power of firms. Labor market regulation protects these workers against those firms.

2.2 Solution

The model is solved by backward induction.

i) In stage 3, the labor market is either regulated or flexible, and the share of individuals with strong family ties is given.

Flexible labor market

If the labor market is flexible, individuals with weak family ties obtain a wage equal

¹²The latter can take a variety of forms, including the distortionary cost of taxation needed to provide unemployment subsidies for those not employed in distorted labor market. We do not explicitly model this channel.

¹³The important assumption here is that mobility costs decrease wages. This property could be obtained in a search and matching model à la Mortensen and Pissarides, see e.g. Pissarides (2000).

to 1 by moving at no cost. Their utility level is

$$U_F^W = 1. \quad (1)$$

Individuals with strong family ties get a wage equal to 1 if they decide to leave their initial location, but the move costs them $2\Delta(\sigma)$. Therefore, their reservation wage, which is necessarily non negative, is equal to $\max[0, 1 - 2\Delta(\sigma)]$. Thus individuals with strong family ties get a wage equal to 0 and stay in their initial location if $\Delta(\sigma)$ is larger than $1/2$. In that case, their utility is equal to the valuation of family ties, $\Delta(\sigma)$. If $\Delta(\sigma)$ is smaller than $1/2$, two possibilities can arise.

1. If their productivity in their initial location is larger than their reservation wage, equal to $1 - 2\Delta(\sigma)$, they keep their job in their initial location. In that case, they are paid their reservation wage and they are *immobile*. Their utility is equal to their reservation wage plus the valuation of family ties, i.e. $1 - 2\Delta(\sigma) + \Delta(\sigma) = 1 - \Delta(\sigma)$

2. If their productivity in their initial location is smaller than their reservation wage, individuals with strong family ties are not hired. Since $\Delta(\sigma) < 1/2$, individuals with strong family ties prefer to move and get a utility equal to $1 - \Delta(\sigma)$. In conclusion, when the labor market is flexible, the utility of individuals with strong family ties is

$$U_F^S = \max[\Delta(\sigma), 1 - \Delta(\sigma)]. \quad (2)$$

Rigid labor market

If the labor market is regulated, the government sets a minimum wage and job protection. For every worker, the probability to get a job offer in the firm located in his/her initial birth place is equal to the probability to draw a productivity y larger than the reservation productivity R . With the uniform distribution, this probability is equal to $1 - R$. If the productivity is higher than R , individuals can get the minimum wage w in their birth place, or leave the firm and obtain a wage equal to $1 - c$ elsewhere, where c denotes deadweight losses associated with job protection.¹⁴ R and w are determined endogenously below in equilibrium. When the productivity is lower than R , individuals get either zero income if they do not move, or a wage equal to $1 - c$ if they move. Individuals

¹⁴ Assuming that firms can make counter offers so that only weak family ties workers with productivity $y < 1 - c$ and strong family ties workers with productivity $y < 1 - c - 2\Delta(\sigma)$ move, would not change the qualitative results of the model.

with weak family ties get the expected utility

$$U_R^W = (1 - R) \max(1 - c, w) + R(1 - c). \quad (3)$$

The expected utility of individuals with strong family ties is

$$U_R^S = (1 - R) \max[w + \Delta(\sigma), 1 - c - \Delta(\sigma)] + R \max[\Delta(\sigma), 1 - c - \Delta(\sigma)] \quad (4)$$

ii) In stage 2, people vote on the labor market policy: either regulation or flexibility. The share of individuals with strong family ties, chosen in stage one, is given. There are only two types of voters, so that the median voter can have either strong family ties or weak family ties. We assume that the owners of the firms do not vote. If they did they would always prefer labor market flexibility regardless of the level of family ties therefore they have a dominant strategy to vote for flexibility. Their share of votes should be simply added to those who vote for *laissez-faire*.¹⁵

- Individuals with weak family ties obtain $U_F^W = 1$ under labor market flexibility, and $U_R^W < 1$ under labor market regulation.¹⁶ When the labor market is rigid, the expected utility of workers with weak family ties is smaller than 1 because $R \in [0, 1]$ and the wage cannot be larger than $1 - c$, otherwise firms would get negative profits. Therefore, individuals with weak family ties always prefer labor market flexibility. This implies that the outcome of the vote is labor market flexibility if the share of people with strong family ties, σ , is smaller than $1/2$.

- Now, consider the case where $\sigma > 1/2$, so that the median voter has strong family ties. For the sake of simplicity, assume that all individuals with strong family ties are immobile if the majority of the population has strong family ties under flexible labor market. According to equation (2), this requires that:

Assumption 1: $\Delta(1/2) > \frac{1}{2}$.

This assumption implies that when the labor market is regulated, workers with strong family ties do not move. This case is easier to illustrate and we do so in the text. The general case without that assumption is in the appendix.

¹⁵ In case workers own stocks of firms then some of them would face a trade off between their interest as stock holders and those as workers. We do not explore this extension here. In most countries the percentage of individuals who hold stocks of individual firms is very small.

¹⁶ When the labor market is rigid, the expected utility of workers with weak family ties is smaller than 1 because $R \in [0, 1]$ and the wage cannot be larger than $1 - c$. Otherwise firms would get negative profits.

Assumption 1 implies that the expected utility of individuals with strong family ties when the labor market is flexible and when $\sigma > 1/2$ is:

$$U_F^S = \Delta(\sigma) \quad (5)$$

On the other hand, the expected utility in the regulated scenario is given by:

$$U_R^S = (1 - R)w + \Delta(\sigma). \quad (6)$$

Comparison of equations (5) and (6) shows that those with strong family ties prefer a regulated labor market rather than a flexible one.

The optimal labor market regulation is the set of values of the minimum wage w and of the reservation productivity R that maximizes the expected utility of workers with strong family ties, as defined by equation (6) and subject to the zero profit condition

$$\int_R^1 (y - c - w)dy = 0. \quad (7)$$

It is easily checked that the solution is

$$R = c \text{ and } w = \frac{1 - c}{2} \text{ which implies } w > R \quad (8)$$

The solution shows that labor market regulation comprises a binding minimum wage and job protection which forces firms to keep employees whose productivity is lower than their labor cost. In this equilibrium, every worker with strong family ties can be either employed (with probability $1 - c$) or unemployed (with probability c) and remains in his initial location. Profits are equal to zero. The wage is smaller than 1 and also smaller than the wage under flexible labor markets. Employment is equal to $1 - \sigma c$, since all individuals with weak family ties are employed (the share of individuals with strong family ties is equal to σ , and a share c of individuals with strong family ties are unemployed). Thus employment is lower when the labor market is regulated, since employment is equal to 1 when the labor market is flexible. Workers with strong family ties get the expected utility (see equations (6) and (8)):

$$U_R^S = \frac{(1 - c)^2}{2} + \Delta(\sigma) \quad (9)$$

which is larger than $\Delta(\sigma)$, the utility they would get if the labor market were flexible.

In conclusion, the outcome of the vote is for market regulation if $\sigma > 1/2$; and for labor market flexibility otherwise.

iii) In stage 1, individuals choose their family values with perfect foresights. If they anticipate that the share of individuals with strong family ties is smaller than $1/2$, they know that labor market flexibility will prevail. Otherwise, the outcome of the vote will be labor market regulation. Therefore, the payoff of individuals with strong family ties is

$$\begin{cases} \max[\Delta(\sigma), 1 - \Delta(\sigma)] & \text{if } \sigma \leq 1/2 \\ \Delta(\sigma) + \frac{(1-c)^2}{2} & \text{if } \sigma > 1/2, \end{cases}$$

and the payoff of individuals with weak family ties is¹⁷

$$\begin{cases} 1 & \text{if } \sigma \leq 1/2 \\ 1 - c & \text{if } \sigma > 1/2. \end{cases}$$

Thus, the utility gains of choosing strong family ties rather than weak family ties are

$$\Gamma(\sigma) = \begin{cases} \max[\Delta(\sigma), 1 - \Delta(\sigma)] - 1 & \text{if } \sigma \leq 1/2 \\ \Delta(\sigma) - \frac{1-c^2}{2} & \text{if } \sigma > 1/2. \end{cases}$$

In a Nash equilibrium, every individual takes σ as given and chooses strong family ties if the gains of doing so are positive, and weak family ties otherwise. At this stage, it turns out that there exists an equilibrium with weak family ties only if we make the relatively innocuous:¹⁸

Assumption 2: when the share of population with strong family ties goes to 0, the utility gains induced by strong family ties are smaller than the maximum wage gains obtained by changing of location: $\Delta(0) < 1$.

2.3 Equilibria

Under assumptions 1 and 2, Figure 1 shows the function $\Gamma(\sigma)$ which implies two stable Nash equilibria. There is an equilibrium (point A on Figure 1) where everybody chooses weak family ties and then vote for labor market flexibility. In that case, the labor market is competitive: everyone is paid his marginal productivity. Labor mobility is high since

¹⁷When the labor market is rigid, the minimum wage, $w = (1 - c)/2$, obtained by immobile workers, is smaller than $1 - c$, the wage of mobile workers. This implies that individuals with weak family ties are always mobile.

¹⁸If this assumption were not satisfied then the value of family ties in a society where nobody else values them is larger than the maximum salary that one can obtain in the market.

everyone changes his location in this equilibrium. On the other hand, there is another equilibrium (point B on Figure 1) where everyone chooses strong family ties and then vote for stringent labor market regulation. The labor market is monopsonistic because workers are immobile. This is the reason why people vote for stringent labor market regulation.

Production, employment and wages are lower with rigid labor markets than with flexible labor markets. However, it is important to remark that the equilibrium with flexible labor markets does not necessarily Pareto-dominate the equilibrium with rigid labor markets. Actually, the equilibrium with rigid labor markets and strong family ties dominates if $\Delta(1) > 1 - \frac{(1-c)^2}{2}$, since the expected utility is $\Delta(1) + \frac{(1-c)^2}{2}$ in the equilibrium with strong family ties and 1 in the equilibrium with weak family ties. Otherwise, the equilibrium with weak family ties yields higher welfare. Accordingly, the economy can be coordinated on an equilibrium with too rigid labor markets, when $\Delta(1) < 1 - \frac{(1-c)^2}{2}$, but also on an equilibrium with too flexible labor markets, when $\Delta(1) > 1 - \frac{(1-c)^2}{2}$. As shown in Figure 2, it turns out that labor market regulation is the preferred equilibrium if the valuation of strong family ties when everyone has strong family ties, $\Delta(1)$, is high relative to c , the cost of labor market regulation.

A slightly different way of rephrasing this result is that in countries or historical periods when family ties can bring about great gains then the benefits of family ties may compensate for the loss of efficiency caused by labor market regulations.

2.4 The dynamics of family values

Following the seminal papers of Bisin and Verdier (2000, 2001), we assume that paternalistic parents wish to transmit their own values to their children. Suppose that each individual lives for one period, has one child, and has payoffs as before. Her child inherits her family values with probability $p > 1/2$ and is free to choose her family values with probability $1-p$. As it will be clear below, $p > 1/2$ ensures that the transmission of family ties influences the dynamics of labor market regulation. When $p \leq 1/2$, the stickiness in the transmission of family ties is not sufficient to influence the choice of labor market regulation.

The sequence of events outlined above is now repeated in each period with an infinite horizon, with the only change being that only a fraction $1-p$ of the population chooses

family values; a fraction $p\sigma_{t-1}$ is constrained to have strong family ties and a fraction $p(1 - \sigma_{t-1})$ to have weak family ties. In other words we add some stickiness to the transmission of family ties. Not everyone can freely choose a set of family ties every generation.

- If $\sigma_0 > 1/2p$, the share of individuals with strong family ties is necessarily larger than $1/2$ in period 1. Then, the median voter chooses to regulate the labor market and every individual is better off with strong family ties. Since there are at least $p(1 - \sigma_0)$ individuals with weak family ties in period 1, the share of individuals with strong family ties in period 1 is

$$\sigma_1 = 1 - p(1 - \sigma_0) > 1/2.$$

Then, in periods $t \geq 1$, the labor market is regulated and the share of individuals with strong family ties

$$\sigma_t = 1 - p^t(1 - \sigma_0).$$

converges to one when t goes to infinity.

- If $\sigma_0 < 1 - (1/2p)$, the same type of reasoning shows that the economy has a flexible labor market in period $t > 0$ and that

$$\sigma_t = \sigma_0 p^t,$$

converges to zero when t goes to infinity.

- If $\sigma_0 \in [1/2p, 1 - (1/2p)]$, there are two possible equilibria in periods $t > 0$ as far as σ_{t-1} remains in the interval $[1/2p, 1 - (1/2p)]$. If σ_{t-1} does not belong to this interval, the dynamics of σ after date t is described by one of the two cases described above.

This simple analysis shows how societies starting with a large share of individuals with strong family ties have strong labor market regulations, whereas societies starting with weak family ties have flexible labor markets. This analysis shows a two way interaction between culture and institutions.

3 Family ties and labor market regulation: cross country evidence

Our model predicts that individuals with stronger family ties prefer and choose a more stringent labor market regulation. We motivate our analysis by showing a strong correlation between the strength of family relationships and labor market regulations (and also desire for regulations) across countries. An analysis of second generation immigrants' economic outcomes and attitudes toward regulation in the next section will help to further limit the possibility that our results are driven by omitted variables and reverse causality. In the last section, we use regional variation in family structures to document the existence of a strong correlation between the structure of the family in the Middle Ages, current family arrangements and the individual desire for regulation.

3.1 Data

3.1.1 Family ties

We measure the strength of family ties by using a series of objective and subjective measures of family ties. We use two main data sources: the *World Values Survey* (WVS) and the *Survey of Health, Ageing and Retirement in Europe* (SHARE).

The WVS is an international social survey of four waves 1981-84, 1990-93, 1995 and 1999-2003, denoted henceforth 1980, 1990, 1995 and 2000. This survey provides, among other things, a wide range of subjective indicators on the relationship between parents and children and, as an objective measure of family attachment, whether the individual lives with his/her parents. We measure family strength using the following five measures:

i) living with parents: the question is an objective indicator of family strength and measures whether a young adult is living at home with his/her parents. Reher (1998) in studying differences between weak and strong family ties in Europe indeed claims that "the strength and weakness refers to cultural pattern of family loyalties, allegiances, and authorities which are reflected in demographic patterns of coresidence with adult children and older family members".

ii) respect parents: the question probes whether the respondent agrees with one of the two statements (taking the values of 1 and 2 respectively): 1) regardless of what the

qualities and faults of one's parents are, one must always love and respect them; 2) one does not have the duty to respect and love parents who have not earned it.

iii) make parents proud: the question asks the respondents to agree or disagree (on a scale from 1, agree strongly, to 4, strongly disagree) with the following statement: one of the main goals in life has been to make my parents proud.

iv) parents' responsibility: the question investigates whether the respondent agrees with one of the two statements (taking the value of 1 and 2 respectively): 1) It is the parents' duty to do their best for their children even at the expense of their own well being, 2) Parents have a life on their own.

v) obey parents: the question asks whether obedience is an important quality for children and can take the value of 1 if it is indeed important and 0 if it is not.

vi) family important: this question assesses how important the family is in one person's life and can take values from 1 to 4 (with 1 being very important and 4 not important at all).

We recode all the questions so that a higher number implies a stronger attachment to the family and collapse the data at the country level to be able to correlate them to measures of labor market regulations across countries.

The SHARE database is a cross-national database that provides micro data on health, socio-economic status and the social and family network of individuals, aged 50 or over, for 14 European countries.¹⁹ For our purposes, the SHARE survey has the advantage of collecting detailed information on child-parent geographic proximity. From this survey we constructed three different indicators of family attachment at the country level:²⁰ the first indicator measures the fraction of adult children (older than 24), who live 5 Km or closer to their family. The second indicator measures the average age at which the young adult left home, and the third indicator measures the frequency of contacts parents have with their children (this variable, increasing with frequency, is coded on a scale from 1 (never) to 7 (daily))²¹.

¹⁹This paper uses the second release of the 2006 wave, which includes the following countries: Austria, Belgium, Czech Republic, Denmark, France, Germany, Greece, Ireland, Italy, Netherlands, Poland, Spain, Sweden, Switzerland.

²⁰We constructed the indicator using the information on the first child; the survey also reports information for the other children. The results remain valid when we look at the second or third child or an average of all the children.

²¹The variable can take the following values: never (1), less than once a month (2), about once a month

3.1.2 Labor market regulation and desire for labor market regulation

We measure regulation in the labor market by focusing on the labor market institutions analyzed in the model: firing costs and the stringency of the minimum wage regulation. Firing costs are measured using the index of the World Bank for the year 2004 (see Botero et al., 2004). This index measures firing costs in terms of weeks of salary. It is based on three components: *i*) the notice period for redundancy dismissal after 20 years of continuous employment, *ii*) the severance pay for redundancy dismissal after 20 years of employment and *iii*) the legally mandated penalty for redundancy dismissal. We mainly focus on this indicator because it covers much more countries than the OECD employment protection index, and it displays more heterogeneity than the World Bank indicator of the difficulty of firing. The index can take values from 0 to 200.²²

The stringency of the minimum wages regulation is measured through a composite index constructed by the ILO.²³ The index combines information *i*) on the level of the minimum wage and *ii*) on the existence of legal minimum wages and the extent of potential derogation. The index refers to the year 2006. The first component of the index, the level of the wage floor, is measured as the monthly minimum wage expressed in US dollars. To make this measure comparable across countries, we calculate the share of the monthly minimum wage as a function of per capita income in 2006. Income per capita is taken from the World Bank. The second component of the index measures the stringency of the minimum wage legislation, that is the extent to which the state directly regulates by law the labor market instead of letting social partners negotiate. This component can take the following values:

- **1** if there is a legal statutory minimum wage and if the minimum wage is set at the national level without any derogation.

(3), about every two weeks (4), about once a week (5), several times a week (6), daily (7).

²²For robustness checks, we also consider the OECD employment protection index. We take the most recent indicator in 2008, covering 33 countries for which we have observations on family ties. The recent trends in labor market regulations are that countries with more rigid labor markets have introduced some flexibility for particular population groups. The question of why some countries impose a more rigid regulation for some groups than on others is beyond the scope of this article. But we check that the legislation on temporary contracts is still more stringent in countries with stronger family ties than in countries with weak family ties. The indices on regular contracts and temporary contracts ranges from 0 for the least stringent regulation to 6 for the most restrictive legislation. The index on temporary contracts covers both fixed term contracts and all other kinds of short term contracts.

²³This index is described more precisely in Aghion, Algan and Cahuc (2011).

- **0.5** if there is a legal statutory minimum wage but with derogations by age, qualification, region, sector or occupation; or if the wage floor is set by collective bargaining but extended to all workers.
- **0** if the wage is set by collective bargaining and only applies to the unionized workers.

The overall index is the product of these two components.

We measure the desire for labor market regulation aggregating at the country level the following two subjective measures. We measure the demand for job security using the following question in the four waves of the WVS “*Here are some more aspects of a job that people say are important. Please look at them and tell me which ones you personally think are important in a job?: Good Job Security*”. The answers take on the value 1 if job security is mentioned and zero otherwise. The demand for wage regulation is measured by using the *International Social Survey Program*. The ISSP is a compilation of surveys, covering all OECD and Eastern European countries, devoted each year to different specific topics such as religion, social networks or the role of government. A specific ISSP survey on “*The role of government*” was carried out in 1996, providing a specific question on the regulation of wages: “*Here is a list of potential government actions for the economy: Control wages by law?*”. The answers can take on values from 1, strongly agree, to 4, strongly disagree. To ease the interpretation we recode the question as a dummy taking the value of 1 if the respondent (strongly) agrees and 0 if he/she (strongly) disagrees. The results remain unchanged with the original coding.

3.2 Cross country correlations

Figure 3 shows the positive cross-country correlation between the two measures of labor market regulation (firing costs and the minimum wage) and the objective indicator of family ties, measured by the fraction of young adults living in the parental home.²⁴ Countries with strong family ties tend to have higher firing costs and also more stringent regulation of the minimum wage.²⁵ Figure 4 shows the relationship between desire

²⁴We do the cross-country analysis using the objective measures of family ties. The results with the subjective measures are very similar and are available from the authors. The correlations between the different measures of family ties are very strong and are reported in Table 1.

²⁵Figure 3 bis shows the relationship between family ties and the alternative OECD index of employment protection, distinguishing between regular and temporary contracts. We find the same correlation

for regulation (demand for wage and job security) and the strength of family ties. The correlation between those labor market institutions and the demand for those types of regulation is substantial, suggesting to probe into the determinants of the demand for regulation.

In the Appendix (Table B2) we report the correlations with additional controls. We include legal origin, which is the traditional alternative theory to explain regulation and its economic consequences (see Botero et al., 2004; or Laporta et al., 2008). We also include the (ln)-country average population over the period 1980-2000 (taken from the World Bank). As stressed by Mulligan and Shleifer (1995), the population density might be crucial to explain the supply of regulation. The relationship between the labor market regulation or desire for regulation and family ties remains positive and statistically significant at the 1 or 5 percent level.²⁶ The economic impact of family ties is sizeable. A one standard deviation increase in the strength of family ties (0.104) is associated with a 10.4 percent increase in firing costs (equal to 22 percent of the sample mean of the firing cost variable). A one standard deviation increase in the strength of family ties also explain 17 percent of the sample mean of the minimum wage variable and 9 percent of the sample mean of the demand for job security²⁷.

In Figures 5 and 6, we show the correlations between labor market regulation (and desire for labor market regulation) and the three additional objective measures of family attachment constructed from the SHARE survey. The picture found with these additional measures is very consistent with our previous finding: countries with strong family ties demand and choose more regulated labor market institutions.

pattern. The cross-country correlation between the legislations on temporary and on regular contracts is modest, reaching 0.388. But we find that OECD countries with strong family ties, in particular in Southern European countries, have also more stringent legislation on temporary contracts.

²⁶The only relationship that is no longer statistically significant is with the demand for wage regulation, but this is most likely due to the low number of observations.

²⁷Table B2 bis shows the results with the OECD employment protection indexes. We report the results for temporary and regular contracts and also for the global index (an average of the two types of legislations weighted by the share of workers covered by each contract.) We still find a statistically significant correlation with family ties, at the 10 percent level though, but the number of observations is reduced by half when the sample includes OECD countries only.

4 Evidence from US immigrants

Cross-country correlations are only illustrative because omitted variables and reverse causality may influence the relationship we are interested in. The omitted variable problem is obvious: many other variables besides family ties may explain differences in labor market institutions across countries. In order to avoid this problem one could look at within country evidence comparing preferences for labor market regulation at the individual level (i.e. running individual level regressions with country fixed effects). However even this empirical strategy suffers from a problem of reverse causality. For instance somebody with low productivity and unwilling to move because of "laziness" may justify to himself (and/or to the interviewer) his/her lack of effort with an attachment to his/her family and a desire to stay home.

We address both concerns by looking at immigrants in the US. We associate to each immigrant the family values of his/her country of origin, as measured by objective and subjective measures of family ties in the World Value Survey. Family values attributed to any immigrant are those of the country of origin and not those that he/she expresses (and that therefore could be caused by his/her special circumstances.) We look at second generation immigrants (individuals who are born and raised in the US), because problems of disruption and selection due to immigration are more limited compared to the first generation. We provide evidence on both immigrants outcomes (unemployment, mobility and wages) and their desire for labor market regulation. We show that immigrants coming from more familistic societies are less mobile, face a wage and employment penalty and also ask for more government regulation of wages and job security.²⁸ The results hold not only when we use the objective measure of family ties but also the five different subjective measures calculated from the World Values Survey.

4.1 Data and empirical specification

We use two main datasets: the March Supplement of the Current Population Survey to study immigrants' economic outcomes and the General Social Survey (GSS) to study

²⁸The use of immigrants (first or second generation) to study the importance of culture on economic behavior is becoming relatively standard in the analysis of culture. See Alesina and Giuliano (2010), Algan and Cahuc (2005, 2009), Antecol (2000), Carroll, Rhee and Rhee (1994), Fernandez and Fogli (2006,2009), Giuliano (2007) and Guiso, Sapienza and Zingales (2006) among others.

immigrants' attitudes towards labor market regulation.

The March Supplement of the Current Population Survey (CPS) is the only recent available dataset in which individuals were asked (starting from 1994) about their parents' country of origin.²⁹ We define second generation immigrants by looking at the country of origin of fathers' respondent in order to maximize the number of observations.³⁰ We pool fifteen years of data to have a higher number of observations. We use the CPS to study the following outcomes predicted by the model: geographical mobility, unemployment and wages. In the CPS we do have data on almost all countries covered in the World Values Survey.³¹ Descriptive statistics are provided in Table B1.

The General Social Survey covers the period 1972-2010 and provides information on the place of birth and the country of origin of the respondent's forbearers since 1977. The GSS variable for the country of origin reads as follows: "From what countries or part of the world did your ancestors come?". The individual can report up to three countries of origin by order of preference. Two respondents out of three report only one country of origin. We select the GSS ethnic variable that captures the country of origin to which the respondent feels the closest to make the comparison between countries of origin interpretable. To maximize the number of observations we combine all generations, therefore we define an immigrant as a person with at least one ancestor (parent or grand parents) born abroad. The descriptive statistics are reported in Table B1 in the Appendix.

The GSS provides specific questions related to attitudes towards job security and regulation. Preferences for job security are measured by the question: "Would you please look at this card and tell me which one thing on this list you would most prefer in a job? No danger of being fired". The answer is ranked from 1, for the most important characteristic, to 5 for the last important. Attitudes toward regulation of jobs and wages are given by the following two questions: "Here are some things the government might do

²⁹The Census reports the information about the father's country of origin until 1970.

³⁰The CPS also reports the country of origin of the mother, but the sample size would be smaller due to a much higher number of missing observations.

³¹The CPS has data on second generation individuals from the following countries of origin: Puerto Rico, Canada, Mexico, El Salvador, Dominican Republic, Argentina, Brazil, Chile, Colombia, Peru, Uruguay, Venezuela, Finland, Norway, Sweden, England, Ireland, Northn Ireland, Belgium, France, Netherlands, Switzerland, Greece, Italy, Portugal, Spain, Austria, Slovakia, Czech Republic, Germany, Hungary, Poland, Yugoslavia, Latvia, Lithuania, Tussia, Ukraine, China, Taiwan, Japan, South Korea, Indonesia, Philippines, Singapore, Vietnam, India, Bangladesh, Pakistan, Iran, Jordan, Turkey, Egypt, Morocco, Nigeria, South Africa, Australia and New Zealand.

for the economy: Supporting declining industries to protect jobs". "Here are some things the government might do for the economy: Regulate wages". The answers range from 1 for strongly agree, 2 for agree, 3 for neither, 4 for disagree to 5 for strongly disagree. We recode all the questions so that a higher number is associated with a higher desire for regulation.

For both attitudes and labor market outcomes, we run the following OLS or probit (depending on the nature of the left hand side variable) regressions:

$$Y_{ic} = \alpha_0 + \alpha_1 family_values_c + \alpha_2 X_i + \delta_s + \varepsilon_{ic}$$

where Y_{ic} is our variable of interest for an immigrant i whose forbearer was born in country c . X_i are individual controls, which vary according to the nature of the left hand side variable, and $family_ties_c$ are different measures of family ties calculated from the WVS in the country of origin. We also control for a full set of state dummies³². All standard errors are clustered at the country of origin level.

4.2 Results

Tables 2 to 4 report the evidence obtained with the CPS for the following labor market outcomes of US immigrants: mobility, unemployment and log real hourly wages. Mobility is defined as a dummy equal to 1 if the individual moved from/in a different state, or abroad in the last five years. Unemployed is a dummy equal to 1 if the person is unemployed. Log hourly wage is defined as total wage income divided by the number of hours worked in a year,³³ and corrected for inflation.

We regress each outcome on the different measures of family ties. The mobility regression (Table 2) controls for education, marital and employment status, real family income, number of children in the household, in addition to gender, race and a quadratic term for age. The standard errors are clustered at the country of origin level. Our specification also includes state dummies to take into account local labor market characteristics of the area where immigrants live that could drive the results. Although we do not report

³²When we use the GSS we include region fixed effects, since the information about the state of residence is not available in the publicly available version.

³³The CPS has information on both the number of weeks worked in a year and the number of hours usually worked in a week.

them explicitly in here, we find that the estimated coefficients for the control variables are generally as expected.³⁴ Unemployed individuals are more likely to move (most likely to find a better job). Less educated people are less mobile and higher income tends to discourage mobility. Married people tend to move less, similarly to women (although the gender effect is not significant). The results are significant and with the expected sign for each measure of family values.

Table 3 reports the results for the probability of being unemployed. People coming from familistic countries should have a higher unemployment rate, as they are less willing to migrate and have a higher reservation wage. We find that the probability of being unemployed is indeed substantially higher³⁵ for immigrants coming from familistic countries.³⁶

Table 4 reports a standard Mincer wage regression where log hourly wages are regressed on education and a quadratic in potential experience (defined as age minus number of years of education minus six). We also control for marital status and gender. Higher experience increases wages, as expected, together with education. Single people and women tend to have lower wages. All the different measures of family values have a significant effect on wages: second generation immigrants coming from familistic countries have lower wages as predicted by our model.

Independently of how we measure family ties, we always find a significant effect of country of origin's measures of family ties in the determination of immigrants' outcomes. In terms of magnitude of the results, we can easily compute the impact of a one standard deviation increase in different measures of family ties: for example, for the mobility equation, an increase in one standard deviation of the variable "living with parents" leads to a decline of 0.012 of the mobility variable, which is equivalent to 12 percent of the average of this variable. The results for the other family values variables are very similar and can explain between 7 and 11 percent of the mean of the mobility variable. The

³⁴The estimates for the controls are available upon request.

³⁵We do not find a significant effect on the variable indicating the fraction of people living at home in the country of origin. Note that this variable is however significant when we look at the probability of being unemployed for second generation immigrants in the Census 1940, 1960 and 1970. The results are reported in Tables B3-B5 of Appendix B.

³⁶This result is also in line with Bentolila and Ichino (2008), who find that the losses associated with unemployment are much lower in Mediterranean societies with strong family ties, as the family provides insurance.

effects of the family variables from the country of origin are of comparable magnitude for the unemployment variable and a bit smaller for wages (this could be due to the fact that since individuals do not move to stay close to their families they might decide to invest less in education to start with and have lower wages as a result).

We have used the Current Population Survey, since this dataset is the closest in time to the data on family ties taken from the World Values Survey. As a robustness check, we report in the Appendix (Tables B3 to B5) results for our outcomes of interest, drawn from the Censuses 1940, 1960 and 1970.³⁷ We run the regressions under the assumption that family values observed today have been fairly stable over time, so we assume that they did not change in the last 70 years or so. Our results are remarkably consistent with those found using the Current Population Survey: today as well as 70 years ago, immigrants coming from strong family ties societies tend to have lower mobility rates, lower wages and a higher level of unemployment.

In Tables 5 to 8, we look at the implication of inherited family values on the demand for regulation: according to our model, individuals with strong family attachment should ask for more regulation of jobs and wages. The general social survey contains three questions on labor market regulation. The first question is a generic question on whether job security is the first, second, third, fourth or fifth most important thing in a job. The second question asks the respondent whether he/she believes that the government should regulate wages and the third whether the government should support declining industries (these last two questions are coded on a scale of 1 to 5 from strongly in favour to strongly against³⁸). We recode all the variables so that a higher number indicates stronger desire for regulation. Each regression controls for a quadratic in age, years of education, gender, income, employment and marital status, number of children and region fixed effects.³⁹ Standard errors are clustered at the country of origin level. The results are highly consistent with the previous cross-country estimates. US immigrants coming from strong family ties countries tend to consider job security as a more important characteristic for a job. They are also more likely to believe that the government should save jobs or directly intervene to regulate wages. The effects are statistically significant

³⁷The Census 1950 does not contain the variable on geographical mobility.

³⁸The exact coding is strongly in favour, in favour, neither, against, strongly against.

³⁹The publicly available version of the GSS provide only the region of residence as geographic identifier.

and economically sizeable. A one standard deviation increase in the fraction of adult population living at home in the country of origin can explain 5 percent of the sample average of all the three different measures of desire for regulation. The effect is of sizable magnitude when compared to variables such as income or education. An increase in one standard deviation in the years of education can explain 10 percent of the sample average of the desire for regulation.

Table 8 reports the estimated average effect size (AES) for the three measures of regulation examined in Tables 5-7. We computed the AES following Kling, Liebman, Katz and Sanbonmatsu (2004). Let β^k indicate the estimated family ties coefficient for outcome variable k and σ^k the standard deviation of outcome k . Then, the average effect size is equal to $\frac{1}{K} \sum_{k=1}^K \frac{\beta^k}{\sigma^k}$, where K is the total number of outcome variables. To properly calculate the sample variance of the AES, the coefficient β^k are jointly estimated in a seemingly unrelated regression framework.⁴⁰ The AES estimates confirm the finding when examining the attitudes toward regulation separately: coming from a country where family ties are very strong is associated with more desire for labor market regulation among immigrants. The results are always significant at the 1 percent level, independently of the measure of family ties in the country of origin used.

5 Persistence

One of the basic messages of the present paper is that labor market institutions depend upon deeply rooted cultural values, like family ties. One of the reason why economically apparently "inefficient" institutions persist is precisely because they are consistent with certain cultural values. Thus labor market institutions are persistent to the extent that family values are fairly constant over time. In this section we present evidence showing that indeed family values do not change quickly. We do so in two ways. First, we show that the strength of family ties inherited from countries of origin before 1940 is correlated with the stringency of labor market regulation in the countries of origin at the beginning of the 21st century. Second, we exploit differences in family types across European regions dating back to the Middle Ages, by using the classification of Emmanuel Todd (1990). We match historical family types with current individual family structures, to show a strong

⁴⁰See Clingingsmith, Khwaja and Kremer (2009) for an alternative application and further details.

persistence between family structures in the Middle Ages and family structures today. We also link historical family types to the demand for job regulation using the regional variation provided by Todd. We find strong evidence of persistence between historical family structures and current family structures, and between historical family structures and the demand for regulations.⁴¹

5.1 Values inherited before 1940 and 21st century institutions

In this section, we investigate the persistence of family values and their long lasting impact on labor market regulations, by showing that attitudes toward the family of immigrants arrived in the US before 1940 are related to the labor market regulations in the country of origin at the beginning of the twenty first century. We focus on family values before World War II since the main labor market institutions have been implemented in the post-war period.

The strength of family ties before World War II cannot be observed directly, since there is no survey available on this period. However, we can detect family ties for this period by looking at the family values inherited from their country of origin by U.S. immigrants whose forebears arrived in the U.S. before 1940. We still use the GSS which yields information on the country of origin of immigrants since 1977. In order to get enough observations, we use information on: i) second generation immigrants born before 1940, since their parents immigrated in the U.S. before 1940; ii) third generation immigrants born before 1965, since their grand parents arrived in the U.S. before 1940; iii) fourth generation immigrants born before 1990.⁴²

The GSS does not contain the same variables on family ties as those of the World Values Survey. To measure the strength of family ties we use the following variable: "How often do you spend a social evening with relatives?". The respondent can answer: almost every day, "once or twice a week, several times a month, about once a month, several times a year, about once a year, never". The answer has been coded from 1 to 7 so that a higher frequency of meetings with relatives corresponds to stronger family ties".

⁴¹We cannot link immigrant's outcomes and preferences to the medieval classification of Emmanuel Todd, because the CPS and the GSS do not report region of origin of the immigrants.

⁴²We assume a gap of 25 years between generations.

We run the following OLS regression:

$$Y_{ic} = \beta_0 + \beta_1 X_i + \Phi_c + \varepsilon_{ic}$$

where Y_{ic} is the strength of family ties for an immigrant i whose forebear was born in country c . X_i is a vector of individual controls which includes gender, age, education and income. Φ_c is a country of origin fixed effect, which measures the influence of inherited values on contemporaneous values. Φ_c can be interpreted as a proxy for the family values the immigrants had before 1940 in the country of origin. ε_{ic} is an error term. All standard errors are clustered at the country of origin level. The reference country is Mexico.

Figure 7 shows the correlation between the inherited family ties from the countries of origin before 1940 and the current family ties in the home countries. The strength of family ties for immigrants arrived before 1940 corresponds to the country of origin fixed effects in the microregressions on family ties in the GSS. The current family ties in the home country correspond to the share of adults still living in parental house from the WVS. The correlation is rather steady and equal to 0.48, showing that there is a strong inertia in family values across countries. We next discuss the correlation between the inherited family ties and the current labor market legislations in the home countries. Table 9 shows the OLS estimations controlling for legal origin and population density. The correlation between firing costs in the 2000s and family values prior to 1940 is statistically significant at the 5 percent level. The correlation between the minimum wage legislation and past family values is also statistically significant at the 5 percent level. In contrast, neither legal origins nor population density are statistically significantly correlated with the regulation of labor when we include inherited family values. Moreover, the coefficients associated with past family values are of the same order of magnitude as the ones found with contemporaneous family values in Table B2, suggesting the long lasting effect of family ties on the design of labor market regulation.

5.2 Medieval family structures and current desire for labor market regulation

In this section we further show that family arrangements are persistent over time, by documenting a correlation between medieval family structures and current family arrangements. In addition, we also show that medieval family structures are related to current

desire for regulation. To do so, we use Todd's (1990) classification of medieval families. Todd's classification is particularly appealing since it provides regional variation in the structure of the family. By linking the regional variation in family structures to individual desire for regulation, we further prove that desire for regulation is not driven by other omitted cross country characteristics, since we will be able to control for country fixed effects.

Todd (1990) provides a characterization of family types along two dimensions. The first one refers to the vertical relationship between parents and children. The relationship is said to be "liberal" if children become independent from their parents at an early age and leave their parental home as soon as they get married. The relationship is said to be "authoritarian" if children continue to depend on their parents in adult age and still live with them after marrying. The second principle of organization of the family is the horizontal relationship between siblings, based on inheritance laws or practices. The relationship is egalitarian if siblings receive roughly an equal share of the family wealth after parents' death. On the other hand, the relationship is not egalitarian when the parents can favor one offspring at the expense of the others and transmits family wealth to a single targeted child only.

The combination of these four different patterns of family organization leads to define four family types. The *absolute nuclear family*, characterized by a liberal relationship between parents and children and by unequal inheritance rules. In this context, children become totally independent from their parents when they become adult and form single families with one couple and their children. The *egalitarian nuclear family*, with liberal relationship between parents and children and egalitarian inheritance rules among the children. According to Todd, this family type encourages stronger relations between the family members than the absolute nuclear family, at least until parents' death. The presence of egalitarian inheritance rules therefore encourages the co-residence of different generations, despite the liberal relationship between parents and children. The *extended family*, characterized by an authoritarian vertical relationship and an inegalitarian horizontal relationship between the siblings. The household consists of extended families, where the eldest child and his family stay in the parental home and inherit the family wealth, while the other children remain in the parental home only until they get mar-

ried.⁴³ The fourth type is the *communitarian family*, with both authoritarian vertical relationship and egalitarian inheritance rule between the sons. This type consists of large extended families, with all sons living with their wives in the parental house.⁴⁴

For the case of Europe, Todd provides data at the regional level. There is a significant heterogeneity in family types across European countries. Figure 8 in Appendix shows the different family types at the regional level, using the original Todd's classification.⁴⁵ Absolute nuclear families are more widespread in England, while in Southern European countries families are egalitarian nuclear, extended or communitarian. There is a fair amount of heterogeneity within the same country. In Northern countries like Denmark, Norway or Ireland, we see a division between nuclear egalitarian and extended families. In France, the region Ile de France and the North have egalitarian nuclear families, the West and the East are mainly populated by extended families, whereas communitarian families are the predominant family structures in the South East. The same heterogeneity is at work in countries like Spain, Portugal, Italy, Switzerland or Germany. Todd suggests that the long-term persistence of these family types could explain key economic outcomes such as the European industrial revolutions or the current economic development of regions.⁴⁶

We complement the analyses of Todd (1990) and Duranton et al. (2009) by looking at the relationship between family types in the Middle Ages and the demand for job protection at end of the 20th century; we also look at the correlation between current family arrangements and medieval family structures using individual data from the World Values Survey. We match Todd's European classification of family types with the European countries of the World Values Survey and the International Social Survey Program (ISSP)⁴⁷

⁴³Todd refers to the *extended family* as *stem family*. He also refers to the *incomplete stem family*, the same as the stem family but with more egalitarian inheritance rules (in principle but rarely in practice). We group together the complete and incomplete stem families in our quantitative analysis.

⁴⁴Todd's family classification is based on historical monographies dating back to the Middle Ages, in different regions of Western European countries. These monographies were collected by the church or different legal powers to track their local population and levy taxes. Todd combined these historical monographies with census data in the 1950s and found a very strong persistence of the family arrangement across European regions since the Middle Ages.

⁴⁵See Todd (1990) and Duranton *et al.* (2009) for a detailed presentation of the regional variation for Europe.

⁴⁶See Duranton *et al.* (2009) for details.

⁴⁷The ISSP is a compilation of surveys, covering all OECD and Eastern European countries, devoted each year to different specific topics such as religion, social networks or the role of government. A specific ISSP survey on "The role of government" was carried out in 1996.

datasets at the regional level.⁴⁸ We first document a correlation between the probability for an individual to live at their parents’ place and medieval family structures. As outlined above, with the exception of absolute nuclear families, all the other family structures were favouring the cohabitation of parents and children. From the WVS, we also look at a question on the preference for job security: “Here are some more aspects of a job that people say are important. Please look at them and tell me which ones you personally think are important in a job?: Good Job Security?” The answers take on the value 1 if job security is mentioned and zero otherwise. We then consider a question taken from the ISSP on labor market regulation. In particular the question asks the respondent “Here is a list of potential government actions for the economy: Help Declining Industries and Protect Jobs” and it is coded on a scale from 1 (strongly agree) to 4 (strongly disagree). The question is recoded so that a higher number means more regulation.

Table 10 (column 1) shows the correlation between Todd’s family classification and the probability for a young adult to live at home with parents. We identify the relation across regions by including country fixed effects, while still controlling for individual characteristics. Controls included in the regression are gender, a quadratic in age, education, income, unemployment status, political orientation, religious denomination and country fixed effects. We include one dummy for each family type: absolute nuclear, egalitarian nuclear, extended and communitarian. Absolute nuclear family is the reference group. We find that the probability that individuals live with their parents is significantly higher in regions where the absolute nuclear family was not the dominant type in the Middle Ages. This is consistent with Todd (1990) and also Duranton et al. (2009).⁴⁹

As a second step, we look at the relation between medieval family structure and the contemporaneous desire for regulation (columns 2 and 3). Individuals coming from extended or communitarian family regions tend to be more pro job security than individuals from nuclear family. The effect of extended family and communitarian family on the demand for job security is statistically significant at the 5 percent level, while the

⁴⁸Note that Todd’s data are available only on a map and the region he used do not necessarily correspond to the regional classification reported in the World Value Survey or the ISSP. For that reason we did a country by country adjustment overlaying Todd’s original map with the classification of the WVS and ISSP.

⁴⁹Duranton et al. (2009) study the correlation with average household size in 2000, measured in number of individuals per household, finding consistent results.

relationship with nuclear family is not. Column 3 shows that individuals coming from regions where the family structure was prevalently communitarian also tend to be more supportive of government intervention than individuals coming from nuclear family. The results are statistically significant at the 5 percent level.

Overall all these results are in line with the prediction of the model according to which family values have persistent effects on labor market regulation if the intergenerational transmission of family values is sufficiently strong. Labor market regulations seem to have deep cultural roots since labor market rigidities at the beginning of the twenty first century are correlated with family values prevailing before WWII. We also find evidence of persistence not only between family structures in the Middle Ages and today, but also between medieval family structure and desire for labor market regulation today.

6 Conclusions

Labor market deregulation requires geographical mobility, otherwise firms can take advantage of the immobility of workers and extract monopsony rents. However, geographical mobility requires relatively weak family ties. That is, individuals should not experience a too high utility loss if they need to move away from their family of origin. Such costs may, instead, be high in cultures that value family ties, and therefore family closeness. As a result countries with strong family ties rationally favor a host of labor market regulations, in order to restrict the monopsony power of firms. Family values may evolve over time, although slowly. In places with laissez-faire labor markets, parents have an incentive to teach children the benefits of mobility. In countries with regulated labor markets, the benefit of mobility are much lower and parents can, if they choose to do so, teach the value of family ties, since they come at lower or no costs. Thus we can have two equilibria with a two way causality between family ties and labor market regulation.

We investigate this correlation between family values and attitudes toward labor market regulation and preferences for job security versus free labor market with cross country evidence, individual level evidence drawn from immigrants in the US, together with evidence about persistence in family structures going back to the Medieval period. In all cases we found rather strong confirmation of a correlation between labor market institutions and desire for regulation, and differences in family values/structures. The correlation

between labor market regulation and relatively slow moving cultural traits regarding the family, and the fact that labor market regulation is complementary to certain family values explain the difficulty in liberalizing labor markets. In a sense the relatively low employment and inefficiency associated with labor market regulation is the price that certain countries choose to pay in order to enjoy the benefits of family ties and closeness.

Appendix A

The aim of this appendix is to analyze the model when assumption 1 is not fulfilled in order to provide necessary and sufficient conditions for the existence of every equilibrium.

Stage 3 is described in the main text. Let us describe stages 2 and 1.

Stage 2:

In stage 2, people vote to choose labor market institutions. The share of individuals with strong family ties, σ , chosen in stage 1 is given.

- First, let us analyze the situation where $\Delta(\sigma) > (1-c)/2$. Then, if the labor market is rigid, workers with strong family ties are immobile, since $\Delta(\sigma) > 1 - c - \Delta(\sigma)$ and we can write their expected utility, defined equation (4) in the main text, in the simple following form:

$$U_R^S = (1 - R)w + \Delta(\sigma). \quad (1)$$

We can compute the maximum expected utility that an individual with strong family ties gets with a regulated labor market and compare it with what he gets when labor market are flexible to know when regulation is chosen rather than flexibility. The optimal labor market regulation is the couple of values of the minimum wage w and of the reservation productivity R that maximizes the expected utility of workers with strong family ties, defined by equation (1), subject to the zero profit condition:

$$\int_R^1 (y - c - w)dy = 0. \quad (2)$$

It is easily checked that the solution is

$$R = c \text{ and } w = \frac{1 - c}{2} \quad (3)$$

Then, in case of stringent labor market regulation, workers with strong family ties get the expected utility (from equations (1) and (3)):

$$U_R^S = \frac{(1 - c)^2}{2} + \Delta(\sigma). \quad (4)$$

Comparison of this last equation and equation (2) in the main text implies that a median voter with strong family ties prefers a regulated labor market rather than a flexible labor market when $\Delta(\sigma) > (1 - c)/2$. If $\Delta(\sigma) > 1/2$, $U_F^S = \Delta(\sigma)$ and it is obvious that $U_R^S > U_F^S$. If $(1 - c)^2/2 < \Delta(\sigma) < 1/2$, $U_F^S = 1 - \Delta(\sigma)$ which is smaller than $U_R^S = \frac{(1-c)^2}{2} + \Delta(\sigma)$ if and only if $2\Delta > 1 - \frac{(1-c)^2}{2}$, i.e. if the cost of labor market regulation is small enough with respect to the value of family ties.

- Now, let us analyze the situation where $\sigma > 1/2$ and $\Delta(\sigma) \leq (1 - c)/2$. In this case, individuals with strong family ties move if they do not get a job in their birth place. The optimal labor regulation is the solution to

$$\max_{(R,w)} U_R^S = (1 - R)[w + \Delta(\sigma)] + R[1 - c - \Delta(\sigma)] \quad (5)$$

subject to

$$\int_R^1 (y - c - w)dy = 0. \quad (6)$$

$$w + \Delta(\sigma) \geq 1 - c - \Delta(\sigma) \quad (7)$$

Let us denote by λ and μ the Kuhn and Tucker multipliers associated with constraints (6) and (7) respectively. The first order conditions are

$$1 - c - w - 2\Delta(\sigma) - \lambda(R - c - w) = 0 \quad (8)$$

$$(1 - R) - \lambda(1 - R) - \mu = 0 \quad (9)$$

Suppose that constraint (7) is not binding so that $\mu = 0$. From equation (9), $\mu = 0$ implies that $\lambda = 1$. Then, equations (6) and (8) imply that

$$R = 1 - 2\Delta(\sigma) \text{ and } w = 1 - c - \Delta(\sigma) \quad (10)$$

Substituting this solution for w into equation (7), it turns out that constraint (7) is never binding. Therefore, in the case where $\sigma > 1/2$ and $\Delta(\sigma) \leq (1 - c)/2$, equations (5) and (10) imply that the expected utility obtained by individuals with strong family ties if the labor market is regulated is

$$U_R^S = 1 - c - \Delta(\sigma) [1 - 2\Delta(\sigma)],$$

whereas individuals with strong family ties get

$$U_F^S = 1 - \Delta(\sigma)$$

if the labor market is flexible. Individuals with strong family ties prefer labor market rigidity if and only if

$$1 - c - \Delta(\sigma) [1 - 2\Delta(\sigma)] > 1 - \Delta(\sigma)$$

which is equivalent to

$$c < 2[\Delta(\sigma)]^2.$$

Finally, the situation which arises in stage 2, where individuals vote to choose the type of labor market institution, can be summarized as follows:

- if $\sigma \leq 1/2$, the median voter, who has weak family ties, chooses labor market flexibility.
- if $\sigma > 1/2$, the median voter, who has strong family ties, chooses to regulate the labor market if either $\Delta(1/2) > (1 - c)/2$ and $\Delta(1/2) < \frac{1}{2} - \frac{(1-c)^2}{4}$, or $\Delta(1/2) \leq (1 - c)/2$ and $c < 2[\Delta(1/2)]^2$. Otherwise, the median voter chooses labor market flexibility. Figure A1 depicts the choice of voters when $\sigma \geq 1/2$ in the $(c, \Delta(1/2))$ plane. It turns out that labor market rigidity is chosen if the value of family ties is high with respect to the cost of labor market regulation.

Let us denote by F the set of values of σ such that flexibility is chosen in stage 2.

Stage 1

In stage one, individuals choose their family values. They have perfect foresights. If they anticipate that σ , the share of individuals with strong family ties, belongs to F , they anticipate that labor market flexibility will be the outcome of the vote in stage 2. Otherwise, the outcome of the vote will be labor market regulation. Therefore, the expected utility of individuals with strong family ties is

$$\begin{cases} \max[\Delta(\sigma), 1 - \Delta(\sigma)] & \text{if } \sigma \in F \\ \Delta(\sigma) + \frac{(1-c)^2}{2} & \text{if } \sigma \notin F \text{ and } \Delta(\sigma) > \frac{1-c}{2} \\ 1 - c - \Delta(\sigma) [1 - 2\Delta(\sigma)] & \text{if } \sigma \notin F \text{ and } \Delta(\sigma) \leq \frac{1-c}{2} \end{cases}$$

and the expected utility of individuals with weak family ties is¹

$$\begin{cases} 1 & \text{if } \sigma \in F \\ 1 - c & \text{if } \sigma \notin F. \end{cases}$$

Thus, the utility gains of choosing strong family ties rather than weak family ties are

$$\Gamma(\sigma) = \begin{cases} \max[\Delta(\sigma), 1 - \Delta(\sigma)] - 1 & \text{if } \sigma \in F \\ \Delta(\sigma) - \frac{1-c^2}{2} & \text{if } \sigma \notin F \text{ and } \Delta(\sigma) > \frac{1-c}{2} \\ \Delta(\sigma) [2\Delta(\sigma) - 1] & \text{if } \sigma \notin F \text{ and } \Delta(\sigma) \leq \frac{1-c}{2} \end{cases}$$

In a Nash equilibrium, every individual takes σ as given and chooses strong family ties if the gains of doing so are positive and weak family ties otherwise.

It turns out that there exists a stable Nash equilibrium with $\sigma = 0$ only if assumption 2 is satisfied, i.e. if $\Delta(0) < 1$. If assumption 2 is not fulfilled, it is easily checked that $\Gamma(\sigma) > 0$ for all σ , which implies that there is a single equilibrium with $\sigma = 1$.

If assumption 2 is fulfilled, there is a stable equilibrium with $\sigma = 0$. Then the definition of $\Gamma(\sigma)$ implies that there is either no other stable equilibrium if $\Delta(1) \leq \frac{1-c^2}{2}$ or another stable equilibrium with $\sigma = 1$ if $\Delta(1) > \frac{1-c^2}{2}$.

¹When the labor market is flexible, the minimum wage, $w = (1 - c)/2$, obtained by immobile workers, is smaller than $1 - c$, the wage of mobile workers.

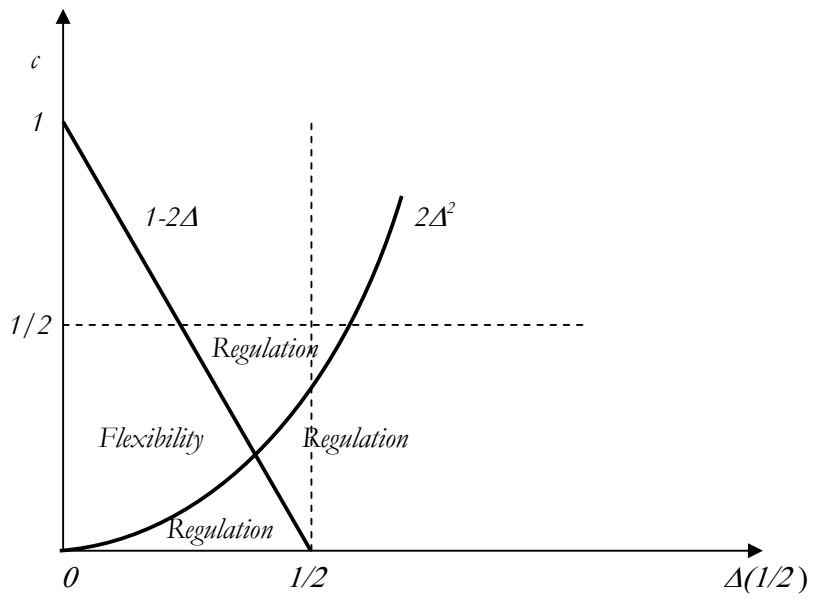

Figure A1: The choice of labor market regulation in stage 2 in the $(\Delta(1/2), c)$ plane when the share of individuals with strong family ties, σ , is larger than $1/2$.
